Elasticity of factorizations in atomic monoids and integral domains

par FRANZ HALTER-KOCH

INTRODUCTION

An integral domain $R$ is called atomic if every non-zero non-unit of $R$ possesses a factorization into a product of (finitely many) irreducible elements of $R$. We are interested in the deviation of $R$ from being factorial. One possible measure of this deviation is the elasticity $\rho(R)$, defined by:

$$\rho(R) = \sup \left\{ \frac{m}{n} \mid u_1 \cdots u_m = v_1 \cdots v_n \text{ for irreducible } u_j, v_i \in R \right\}.$$ 

Clearly, $\rho(R) \in [1, \infty]$, and if $R$ is factorial, then $\rho(R) = 1$.

The concept of elasticity was introduced by R. J. Valenza [20] for rings of integers in algebraic number fields. Using a different terminology, the elasticity of Dedekind domains was investigated by J. L. Steffan [19]. In
a systematic way, the elasticity of various classes of integral domains was studied in [1], [2] and [3].

If $R$ is the ring of integers of an algebraic number field, then $\rho(R)$ depends only on the class group of $R$ (cf. Corollary 1). More generally, if $R$ is a Krull domain, then $\rho(R)$ depends only on the pair $(G, G_0)$, where $G$ is the divisor class group of $R$ and $G_0$ is the set of all divisor classes which contain prime divisors (cf. the Remark after Theorem 2).

If $R$ is an order in an algebraic number field, then $\rho(R) = \infty$ may occur. A necessary and sufficient condition for $\rho(R) < \infty$ is given in Corollary 5. In Theorem 5 we produce estimates for $\rho(R)$, depending on the class group $G = \text{Pic}(R)$ and on the "local" elasticities $\rho(R_p)$ for primes $p$ dividing the conductor of $R$.

Since factorization properties of a domain only depend on its multiplicative structure, it suggests itself to investigate them in a purely multiplicative context. Thus we derive and formulate our main results in the context of commutative and cancellative monoids. This has the advantage of being more general and − what is more important − of revealing the combinatorial structure of factorization properties. Even though most notions and results of the paper concern monoids, the emphasis is on their ring theoretical applications.

§ 1 PRELIMINARIES; $\mu_m$ AND $\rho$

Throughout this paper, a monoid $H$ is a multiplicatively written commutative monoid satisfying the cancellation law, with unit element $1 \in H$. We denote by $H^\times$ the group of invertible elements of $H$; $H$ is called reduced if $H^\times = \{1\}$. If $H_1$ and $H_2$ are monoids, we denote by $H_1 \times H_2$ their direct product, and we view $H_1$ and $H_2$ as submonoids of $H_1 \times H_2$, so that every $a \in H_1 \times H_2$ has a unique decomposition $a = a_1 a_2$, where $a_1 \in H_1$ and $a_2 \in H_2$. For a monoid $H$, we use the notions of divisibility theory in $H$ as introduced in [17; 2.14].

By a factorization of an element $a \in H \setminus H^\times$ we mean a representation of the form $a = u_1 \cdots u_r$, where $r \geq 1$ and $u_1, \ldots, u_r \in H$ are irreducible; we call $r$ the length of that factorization, we denote by $\mathcal{L}_H(a) \subset \mathbb{N}$ the set of lengths of factorizations of $a$, and we set

$$l^H(a) = \min \mathcal{L}_H(a), \quad L^H(a) = \sup \mathcal{L}_H(a) \in \mathbb{N} \cup \{\infty\};$$

finally, we call

$$\rho^H(a) = \frac{L^H(a)}{l^H(a)} \in \mathbb{Q}_{\geq 1} \cup \{\infty\}$$
the elasticity of a (in $H$). For $a \in H^\times$, we set $\rho^H(a) = 1$.

A monoid $H$ is called atomic if every $a \in H\setminus H^\times$ possesses a factorization. For an atomic monoid $H$, we call

$$\rho(H) = \sup\{\rho^H(a) \mid a \in H\} \in \mathbb{R}_{\geq 1} \cup \{\infty\}$$

the elasticity of $H$; we say that $H$ has accepted elasticity if $\rho(H) = \rho^H(a) < \infty$ for some $a \in H$.

For an integral domain $R$, we denote by $R^\star = R\setminus\{0\}$ its multiplicative monoid. We set $\mathcal{L}^R = \mathcal{L}^{R^\star}$, $\mathcal{I}^R = \mathcal{I}^{R^\star}$, $\mathcal{I}^R = \mathcal{I}^{R^\star}$, $\rho^R = \rho^{R^\star}$, and we call $\rho(R) = \rho(R^\star)$ the elasticity of $R$. We say that $R$ has accepted elasticity if $R^\star$ has.

For an atomic monoid $H$ and $m \in \mathbb{N}$, we set

$$\mu_m(H) = \sup\{l^H(a) \mid a \in H\setminus H^\times, \ m \in \mathcal{L}^H(a)\},$$

$$\mu^*_m(H) = \sup\{l^H(a) \mid a \in H\setminus H^\times, \ m = l^H(a)\};$$

the invariants $\mu_m(H)$ were introduced in [12] and also investigated in [7] and [16]. They are connected with the elasticity as follows.

**Proposition 1.** Let $H$ be an atomic monoid, $H \neq H^\times$.

i) For every $m \in \mathbb{N}$ we have

$$\mu^*_m(H) \leq \mu_m(H) = \sup\{l^H(a) \mid a \in H\setminus H^\times, \ m \geq l^H(a)\};$$

if $H$ contains a prime element, then $\mu^*_m(H) = \mu_m(H)$.

ii) We have

$$\rho(H) = \sup\left\{\frac{\mu^*_m(H)}{m} \mid m \in \mathbb{N}\right\} = \sup\left\{\frac{\mu_m(H)}{m} \mid m \in \mathbb{N}\right\} = \lim_{m \to \infty} \frac{\mu_m(H)}{m}.$$ 

iii) The following assertions are equivalent:

a) $H$ has accepted elasticity.

b) There exists some $N \in \mathbb{N}$ such that $\rho(H) = \mu_{Nm}(H)/Nm$ for all $m \in \mathbb{N}$.

c) $\rho(H) = \mu_m(H)/m$ for some $m \in \mathbb{N}$.

**Proof.** i) By definition,

$$\mu^*_m(H) \leq \mu_m(H) \leq \mu_m = \sup\{l^H(a) \mid a \in H\setminus H^\times, \ m \geq l^H(a)\}.$$
If \( a \in H \setminus H^\times \), \( m \geq l^H(a) \) and \( N = L^H(a) \), let \( a = u_1 \cdot \ldots \cdot u_s \) be a factorization of \( a \) of length \( s \leq m \), let \( u_{s+1}, \ldots, u_m \in H \) be any irreducible elements, and set \( a' = au_{s+1} \cdot \ldots \cdot u_m \). Then we obtain \( m \in \mathcal{L}^H(a') \) and \( N \leq N + m - s \leq L^H(a') \leq \mu_m(H) \), which implies \( \overline{\mu_m} \leq \mu_m(H) \).

Now let \( p \in H \) be a prime element, \( a \in H \), \( m \in \mathcal{L}^H(a) \) and \( N = L^H(a) \). If \( l^H(a) = s \leq m \), then \( l^H(ap^{m-s}) = m \), \( L^H(ap^{m-s}) = N + m - s \) and consequently \( N \leq N + m - s \leq \mu_m(H) \), which implies \( \mu_m(H) \leq \mu^*_m(H) \).

ii) The first equality holds by definition; i) implies \( \mu_m(H) = \max \{ \mu_j(H) \mid 1 \leq j \leq m \} \), and therefore the second equality holds.

For the proof of the limit assertion, observe that \( \mu_{n+r}(H) \geq \mu_n(H) + r \) and \( \mu_{nr}(H) \geq r\mu_n(H) \) for all \( n, r \in \mathbb{N} \). Let \( A < \rho(H) \) be a real number and \( N \in \mathbb{N} \) such that \( \mu_N(H) > A \). For \( n \in \mathbb{N} \), \( n \geq N \), set \( n = Nq + r \), where \( q, r \in \mathbb{N}_0 \), \( r < N \), and obtain

\[
\frac{\mu_n(H)}{n} \geq \frac{q\mu_N(H) + r}{qN + r} \geq \frac{q\mu_N(H) + N - 1}{qN + N - 1},
\]

which implies \( \mu_n(H)/n > A \) for all sufficiently large \( n \); thus the limit assertion holds true.

iii) It suffices to prove that a) implies b). Let \( a \in H \) be such that \( \rho(H) = \rho^H(a) \) and \( N = l^H(a) \). Then we have \( mL^H(a) \leq L^H(a^m) \leq \mu_{mN}(H) \), since \( mN \in \mathcal{L}^H(a^m) \), and hence

\[
\frac{\mu_{mN}(H)}{mN} \geq \frac{l^H(a)}{l^H(a)} = \rho^H(a) = \rho(H) \geq \frac{\mu_{mN}(H)}{mN}
\]

for all \( m \in \mathbb{N} \). \( \square \)

Proposition 1 has a counterpart for minimal lengths. For an atomic monoid \( H \neq H^\times \) and \( m \in \mathbb{N} \), we define the following quantities:

\[
s_m(H) = \min \{ l(a) \mid a \in H \setminus H^\times, \ m \in \mathcal{L}^H(a) \},
\]

\[
s'_m(H) = \min \{ l^H(a) \mid a \in H \setminus H^\times, \ m \leq L^H(a) \},
\]

\[
s''_m(H) = \min \{ l^H(a) \mid a \in H \setminus H^\times, \ m = L^H(a) \};
\]

they are connected with the elasticity as follows.
PROPOSITION 2. Let $H$ be an atomic monoid, $H \neq H^\times$. Then we have $\sigma_m'(H) \leq \sigma_m(H) \leq \sigma_m''(H)$ for all $m \in \mathbb{N}$, and

$$\frac{1}{\rho(H)} = \inf \left\{ \frac{\sigma_m(H)}{m} \mid m \in \mathbb{N} \right\} = \inf \left\{ \frac{\sigma_m'(H)}{m} \mid m \in \mathbb{N} \right\} = \inf \left\{ \frac{\sigma_m''(H)}{m} \mid m \in \mathbb{N} \right\}$$

$$= \lim_{m \to \infty} \frac{\sigma_m(H)}{m} = \lim_{m \to \infty} \frac{\sigma_m'(H)}{m} = \lim_{m \to \infty} \frac{\sigma_m''(H)}{m}.$$

Proof. By definition, we have $\rho(H)^{-1} = \inf \{\sigma_m''(H)/m \mid m \in \mathbb{N}\}$, $\rho(H)^{-1} \leq \sigma_m'(H)/m$ and $\sigma_m'(H) \leq \sigma_m''(H)$ for all $m \in \mathbb{N}$. Therefore it remains to prove the limit assertions.

For any $n, r \in \mathbb{N}$, we have $\sigma_{n+r}(H) \leq \sigma_n(H) + r$ and $\sigma_{nr}(H) \leq r\sigma_n(H)$. Let $A > \rho(H)^{-1}$ be a real number and $N \in \mathbb{N}$ such that $\mu_N(H) < A$. For $n \in \mathbb{N}$, $n \geq N$, set $n = Nq + r$, where $q, r \in \mathbb{N}_0$, $r < N$, and obtain

$$\frac{\sigma_n(H)}{n} \leq q\sigma_N(H) + \frac{r}{qN + r} \leq q\sigma_N(H) + \frac{N - 1}{qN + N - 1}$$

which implies $\sigma_n(H)/n < A$ for all sufficiently large $n$. Thus the limit assertion for $\sigma_m(H)/m$ follows; that for $\sigma_m'(H)/m$ is proved in the same way. \(\square\)

The following finiteness result is of central importance.

THEOREM 1. Let $H$ be a monoid such that $H/H^\times$ is finitely generated. Then $H$ has accepted elasticity.

Proof. [3; Theorem 7].

Remark. Let $H$ be a monoid having tame factorizations of degree $N$ as defined in [7]; then we have $\rho(H) \leq N$.

This follows from [7], Remark 2 on p. 688, where the more precise result

$$\mu_H(m) \leq 1 + (m - 1)N$$

is asserted. Since every finitely generated monoid has tame factorizations [7; Prop. 2], this implies again $\rho(H) < \infty$ for every finitely generated monoid $H$. 

§ 2 DIVISOR HOMOMORPHISMS AND COPRODUCTS

Recall from [11], Definition 2.3 that a monoid homomorphism \( \varphi : H \to S \) is called a divisor homomorphism if \( x, y \in H \) and \( \varphi(x) \mid \varphi(y) \) implies \( x \mid y \). If \( \varphi : H \to S \) is a divisor homomorphism, then \( \varphi \) induces an isomorphism \( \varphi^* : H/H^\times \cong \varphi H \), and \( \varphi H \subset S \) is a saturated submonoid, i.e., \( a, b \in \varphi H, c \in S \) and \( a = bc \) implies \( c \in \varphi H \). The factor monoid \( S/\varphi H \) consists of all congruence classes for the congruence \( \sim_\varphi \), defined by \( a \sim_\varphi b \) if \( a\varphi(x) = b\varphi(y) \) for some \( x, y \in H \); its quotient group is denoted by \( C(\varphi) \) and is called the class group of \( \varphi \). \( C(\varphi) \) is an abelian group; we usually write it additively, and for \( a \in S \) we denote by \([a] \in S/\varphi H \subset C(\varphi)\) the class of \( a \). Since \( \varphi H \subset S \) is saturated, we have \([a] = 0\) if and only if \( a \in \varphi H \).

The class group of a divisor homomorphism admits the following group-theoretical description. For a monoid \( H \), let \( Q \) be a quotient group of \( H \), and call \( G(H) = Q/H^\times \) the group of divisibility of \( H \) (corresponding with the notions in ring theory). Clearly, \( G \) is a functor from monoids to abelian groups. If \( \varphi : H \to S \) is a divisor homomorphism, then \( G(\varphi) : G(H) \to G(S) \) is a group monomorphism, and the natural map \( S \to G(S) \) induces a functorial group isomorphism \( C(\varphi) \cong \ker G(\varphi) \).

For any set \( P \), let \( F(P) \) be the multiplicative free abelian monoid with basis \( P \). Let \( G \) be an additive abelian group and \( G_0 \subset G \) a subset; for an element \( S = g_1 \cdots g_s \in F(G_0) \) we call \( \sigma(S) = s \in \mathbb{N}_0 \) the size and \( \iota(S) = g_1 + \cdots + g_s \in G \) the content of \( S \); \( \sigma : F(G_0) \to \mathbb{N}_0 \) and \( \iota : F(G_0) \to G \) are monoid homomorphisms. The monoid \( B(G_0) = \{ S \in F(G_0) \mid \iota(S) = 0 \} \)
is called the block monoid over \( G_0 \); it is a Krull monoid and was investigated in [9] and [10]. Davenport's constant \( D(G_0) \) is defined as \( D(G_0) = 0 \) if \( B(G_0) = \{1\} \), and

\[
D(G_0) = \sup\{ \sigma(B) \mid B \in B(G_0) \text{ irreducible } \} \in \mathbb{N} \cup \{\infty\}
\]
otherwise. If \( G_0 \) is finite, then \( D(G_0) < \infty \); if \( G_0 = \{0\} \), then \( D(G_0) = 1 \); if \( G_0 \neq \{0\} \) and \( B(G_0) \neq \{1\} \), then \( D(G_0) \geq 2 \). If \( \#G = \infty \), then \( D(G) = \infty \) by [9; Prop. 2]. For a survey and recent results concerning \( D(G) \), see [13].
Theorem 2. Let \( \varphi : H \to S \) be a divisor homomorphism of atomic monoids, \( H \neq H^\times \) and \( G = C(\varphi) \). Let \( G_0 \) be the set of all classes \( g \in G \) containing irreducible elements of \( S \).

i) For all \( m \in \mathbb{N} \), we have \( \mu_m(H) \leq \mu_{mD(G_0)}(S) \), and

\[
\rho(H) \leq D(G_0) \rho(S).
\]

ii) Suppose that \( S = \mathcal{F}(P) \) for some set \( P \) and \( D(G_0) \geq 2 \). Then we have

\[
\mu_m(H) \leq \frac{1}{2} D(G_0)m
\]

for all \( m \in \mathbb{N} \), with equality if \( m \equiv 0 \mod 2 \) and \( G_0 = -G_0 \). Moreover, we have

\[
\rho(G) \leq \frac{1}{2} D(G_0),
\]

with equality if \( G_0 = -G_0 \).

Proof. See [12; Theorem 1] for the results concerning \( \mu_m \); the results concerning \( \rho \) are easy consequences. Note that the notion of a divisor homomorphism used in [12] differs slightly from that used here. The proofs given there are valid literally in our case. \( \square \)

Remark. Theorem 2 applies for Krull monoids and hence for Krull domains; see [10] and [14] for the corresponding background material. In particular, we obtain the estimates given in [1; Theorem 2.2]. For convenience we formulate our result in the most interesting case of rings of integers in algebraic number fields, where the class group is finite and every class contains a prime.

Corollary 1. Let \( R \) be the ring of integers of an algebraic number field and \( G \) its class group; then

\[
\rho(R) = \frac{1}{2} D(G).
\]

Corollary 2. Let \( G \) be an abelian group, \( G_0 \subset G \) a subset, \( B_0 = B(G_0) \) and \( D(G_0) \geq 2 \). Then we have

\[
\rho(B_0) \leq \frac{1}{2} D(G_0).
\]
with equality if \( G_0 = -G_0 \).

Proof. By Theorem 1, applied for \( \varphi = (B_0 \hookrightarrow \mathcal{F}(G_0)) \). \( \square \)

Recall that a monoid \( H \) is called \textit{half-factorial} if it is atomic and any two factorizations of an element \( a \in \text{H} \setminus H^\times \) have the same length; note that \( H \) is half-factorial if and only if \( \rho(H) = 1 \). If \( H \neq H^\times \), then \( H \) is half-factorial if and only if \( \mu_m(H) = m \) for all \( m \in \mathbb{N} \).

**Proposition 3.** Let \( H \) be an atomic monoid, \( H \neq H^\times \), and let \( F \) be a half-factorial monoid. Then we have \( \mu_m(H \times F) = \mu_m(H) \) for all \( m \in \mathbb{N} \), and \( \rho(H \times F) = \rho(H) \).

Proof. It suffices to prove the assertion concerning \( \mu_m \). For any \( z \in \text{H} \setminus H^\times \), we have \( \mathcal{L}^H(z) = \mathcal{L}^{H \times F}(z) \), and therefore \( \mu_m(H) \leq \mu_m(H \times F) \).

Let \( a = yq \in H \times F \) be such that \( y \in H \), \( q \in F \) and \( m \in \mathcal{L}^{H \times F}(a) \).

If \( y \in H^\times \), then \( \{m\} \) and hence \( \mathcal{L}^{H \times F}(a) = m \leq \mu_m(H) \); if \( y \notin H^\times \), then \( m = k + l \), where \( k \in \mathcal{L}^H(y) \) and \( \mathcal{L}^F(q) = \{l\} \), which implies \( \mathcal{L}^{H \times F}(a) = l + \mathcal{L}^H(y) \leq l + \mu_k(H) \leq \mu_{k+l}(H) = \mu_m(H) \). In any case \( \mu_m(H \times F) \leq \mu_m(H) \) follows. \( \square \)

For a family of monoids \( (H_\lambda)_{\lambda \in \Lambda} \), we consider their coproduct

\[
H = \bigsqcup_{\lambda \in \Lambda} H_\lambda = \left\{ (x_\lambda)_{\lambda \in \Lambda} \in \prod_{\lambda \in \Lambda} H_\lambda \mid x_\lambda = 1 \text{ for almost all } \lambda \in \Lambda \right\},
\]

together with the canonical embeddings \( \iota_\lambda : H_\lambda \to H \), defined by

\[
\iota_\lambda(x_\lambda) = (\ldots, 1, x_\lambda, 1, \ldots) \in H.
\]

If all \( H_\lambda \) are atomic, then \( H \) is also atomic, and the irreducible elements of \( H \) are (up to associates) the elements of the form \( \iota_\lambda(u_\lambda) \), where \( \lambda \in \Lambda \) and \( u_\lambda \in H \) is irreducible.

**Proposition 4.** Let \( (H_\lambda)_{\lambda \in \Lambda} \) be a family of atomic monoids, and \( H = \prod_{\lambda \in \Lambda} H_\lambda \). Then we have

\[
\rho(H) = \sup\{\rho(H_\lambda) \mid \lambda \in \Lambda\};
\]
if $\rho(H) = \rho(H_{\lambda})$ for some $\lambda \in \Lambda$ such that $H_{\lambda}$ has accepted elasticity, then so has $H$.

Proof. Since $\iota_{\lambda}(x_{\lambda}) \in H$ is irreducible whenever $x_{\lambda} \in H_{\lambda}$ is irreducible, we obtain $\rho(H_{\lambda}) \leq \rho(H)$ for all $\lambda \in \Lambda$ (confer [3; Lemma 6]), and hence $\sup\{\rho(H_{\lambda}) \mid \lambda \in \Lambda\} \leq \rho(H)$.

For the proof of the reverse inequality, we suppose that $r = \sup\{\rho(H_{\lambda}) \mid \lambda \in \Lambda\} < \infty$. For $x = (x_{\lambda})_{\lambda \in \Lambda} \in H \setminus H^\times$, we obtain

$$L^H(x) = \sum_{\lambda \in \Lambda} L^{H_{\lambda}}(x_{\lambda}) \leq r \sum_{\lambda \in \Lambda} h^{H_{\lambda}}(x_{\lambda}) = r h^H(x),$$

and therefore $\rho^H(x) \leq r$, which implies

$$\rho(H) = \sup\{\frac{L^H(x)}{h^H(x)} \mid x \in H\} \leq r.$$ 

If $\rho(H) = \rho(H_{\lambda}) = h^{H_{\lambda}}(x_{\lambda})$, where $x_{\lambda} \in H_{\lambda}$, then $\rho(H) = h^H(\iota_{\lambda}(x_{\lambda}))$. $\square$

Let $H$ be a monoid and $Q$ a quotient group of $H$. A family $H = (H_{\lambda})_{\lambda \in \Lambda}$ of submonoids $H_{\lambda} \subseteq Q$ is called a defining family of $H$, if

$$H = \bigcap_{\lambda \in \Lambda} H_{\lambda},$$

and, for each $x \in H$, the set $\{\lambda \in \Lambda \mid x \not\in H_{\lambda}^\times\}$ is finite. In this case, the mapping

$$\varphi : H \to \prod_{\lambda \in \Lambda} H_{\lambda}/H_{\lambda}^\times,$$

defined by $\varphi(x) = (xH_{\lambda}^\times)_{\lambda \in \Lambda}$, is a divisor homomorphism; see [11; § 3]. We call $C(H) = C(\varphi)$ the class group of $H$. Using this terminology, Theorem 2 and Proposition 4 immediately entail the following corollary.

**Corollary 3.** Let $H$ be an atomic monoid, $H = (H_{\lambda})_{\lambda \in \Lambda}$ a defining family of $H$, where all $H_{\lambda}$ are atomic, and $G = C(H)$. Then we have

$$\rho(H) \leq D(G) \sup\{\rho(H_{\lambda}) \mid \lambda \in \Lambda\};$$

if $G = \{0\}$, then

$$\rho(H) = \sup\{\rho(H_{\lambda}) \mid \lambda \in \Lambda\}.$$
Remark. Corollary 3 applies in particular for atomic domains $R$ having a finite character representation

$$R = \bigcap_{p \in \mathfrak{S}} R_p$$

for some set $\mathfrak{S} \subset \text{spec}(R)$ such that all $R_p$ are atomic. Indeed, in this case the family $(R_p^*)_{p \in \mathfrak{S}}$ is a defining family of $R^*$. The ideal theory of domains having such a finite character representation was investigated in [5]. Perhaps the most interesting case arises if $\mathfrak{S} = \mathfrak{X}(1)(R)$, the set of prime ideals of height 1 of $R$. Following [1], we call $R$ a \textit{weakly Krull domain} if $R = \bigcap\{R_p \mid p \in \mathfrak{X}(1)(R)\}$ is a finite character representation; see [14] for a description of weakly Krull domains by means of generalized divisor theories.

Let $R$ be a weakly Krull domain and $G(R) = G(R^*)$ is its group of divisibility; then there is an exact sequence

$$(*) \quad 1 \rightarrow G(R) \rightarrow \prod_{p \in \mathfrak{X}(1)(R)} G(R_p) \rightarrow C_t(R) \rightarrow 0$$

identifying the $t$-class group $C_t(R)$ with the class group of the family $(R_p^*)_{p \in \mathfrak{X}(1)(R)}$ (see [15; Theorem 4.6]. Therefore Corollary 3 implies [1; Theorem 2.14 and Cor. 2.15]. The conjecture stated in [1] after Cor. 2.15 (on p. 231) is false; we give a counterexample at the end of this paper.

If $R$ is a one-dimensional noetherian domain, then $\mathfrak{X}(1)(R) = \text{max}(R)$, $R$ and all $R_p$ are atomic, and $C_t(R) = \text{Pic}(R)$ is the usual class group. In this case, $(*)$ is proved in [18; Satz (12.6)]. For later use, we state Corollary 3 in this particular case.

**Corollary 4.** Let $R$ be a one-dimensional noetherian domain and $G = \text{Pic}(R)$. Then we have

$$\rho(R) \leq D(G) \sup \{\rho(R_p) \mid p \in \text{max}(R)\}$$

if $G$ is trivial, then

$$\rho(R) = \sup \{\rho(R_p) \mid p \in \text{max}(R)\}.$$
§ 3 T-BLOCK MONOIDS

We recall the concept of T-block monoids as introduced in [8]. Let $G$ be an (additively written) abelian group, $G_0 \subseteq G$ a subset, $T$ a reduced monoid and $\iota : T \rightarrow G$ a homomorphism. We extend $\iota$ to a homomorphism

$$\iota^* : \mathcal{F}(G_0) \times T \rightarrow G$$

by setting

$$\iota^*(g_1 \cdot \ldots \cdot g_n t) = \sum_{i=1}^{n} g_i + \iota(t) \in G,$$

i. e., $\iota^* | \mathcal{F}(G_0)$ is the content already considered. Then

$$\mathcal{B}(G_0, T, \iota) = \{ \alpha \in \mathcal{F}(G_0) \times T \mid \iota(\alpha) = 0 \}$$

is called the $T$-block monoid over $G_0$ with respect to $\iota$. If in particular $\iota(t) = 0$ for all $t \in T$, then $\mathcal{B}(G_0, T, \iota) = \mathcal{B}(G_0) \times T$, where $\mathcal{B}(G_0)$ is the ordinary block monoid. The usefulness of $T$-block monoids is shown by the following proposition.

PROPOSITION 5. Let $H$ be an atomic monoids and $\varphi : H \rightarrow S = \mathcal{F}(P) \times T$ a divisor homomorphism, where $T$ is a reduced monoid and $P$ is any set. Let $G = C(\varphi)$ be the class group of $\varphi$, $G_0 = \{ g \in G \mid g \cap P \neq \emptyset \}$, and for $t \in T$ let $\iota(t) \in G$ be the class of $t$. Then $\mathcal{B}(G_0, T, \iota)$ is atomic, $\mu_m(H) = \mu_m(\mathcal{B}(G_0, T, \iota))$ for all $m \in \mathbb{N}$, and $\rho(H) = \rho(\mathcal{B}(G_0, T, \iota))$. If $G_0$ is finite and $T$ is finitely generated, then $H$ has accepted elasticity.

Proof. Since $\varphi$ induces an isomorphism $\varphi^* : H/H^\times \cong \varphi H$ onto a saturated submonoid of $S$, we may assume that $H \subseteq S$ is a saturated submonoid and $\varphi = (H \hookrightarrow S)$. For $p \in P$, let $\beta(p) \in G_0$ be the class of $p$, and define $\beta : S \rightarrow \mathcal{F}(G_0) \times T$ by $\beta(p_1 \cdot \ldots \cdot p_n t) = \beta(p_1) \cdot \ldots \cdot \beta(p_n) t$. By [8; Prop. 4], $\beta$ induces a surjective homomorphism

$$\beta : H \rightarrow \mathcal{B}(G_0, T, \iota)$$

mapping irreducible elements of $H$ onto irreducible elements of $\mathcal{B}(G_0, T, \iota)$ (whence $\mathcal{B}(G_0, T, \iota)$ is atomic) and satisfying $L^H(a) = L^{\mathcal{B}(G_0, T, \iota)}(\beta a)$ for all $a \in H$. This implies $\mu_m(H) = \mu_m(\mathcal{B}(G_0, T, \iota))$ for all $m \in \mathbb{N}$, and consequently $\rho(H) = \rho(\mathcal{B}(G_0, T, \iota))$. Moreover, $H$ has accepted elasticity if and only if $\mathcal{B}(G_0, T, \iota)$ has. If $G_0$ is finite and $T$ is finitely generated, then $\mathcal{B}(G_0, T, \iota)$ is finitely generated by [8; Prop. 2] and hence has accepted elasticity by Theorem 2. □
Remark. Proposition 2 implies in particular that Krull monoids (and hence Krull domains) have accepted elasticity, provided that the set $G_0$ of divisor classes containing prime divisors is finite; for this particular case see [3; Theorem 10].

Next we investigate the invariants $\mu_m$ and $\rho$ for $T$-block monoids. If $H$ is a monoid and $E \subset H$, then $[E]$ denotes the submonoid generated by $E$.

**Theorem 3.** Let $G$ be an abelian group, $G_0 \subset G$ a subset, $T$ a reduced atomic monoid, $T \neq T^\times$, $\iota : T \to G$ a monoid homomorphism, $U$ the set of irreducible elements of $T$ and $G_1 = G_0 \cup \iota(U)$. Let $B_0 = B(G_0) \neq \{1\}$ be the ordinary block monoid and assume that the $T$-block monoid $B = B(G_0, T, \iota)$ is atomic.

i) For all $m \in \mathbb{N}$, we have $\mu_m(B_0) \leq \mu_m(B) \leq \mu_m(T)D(G_1)$, and

$$\rho(B_0) \leq \rho(B) \leq \rho(T)D(G_1).$$

ii) Suppose that $\iota(U) \subset [-G_0]$; then we have $\mu_m(T) \leq \mu_m(B)D(G_1)$ for all $m \in \mathbb{N}$, and

$$\rho(T) \leq \rho(B)D(G_1).$$

**Proof.** It is sufficient to prove the assertions concerning $\mu_m$.

i) If $b_0 \in B_0$, $b \in B$ and $b \mid b_0$, then $b \in B_0$, and hence $L^B(b_0) = L^B(b)$; this implies $\mu_m(B_0) \leq \mu_m(B)$.

By [8, Proposition 1], the injection $B \hookrightarrow S = F(G_0) \times T$ is a divisor homomorphism; its class group identifies in a natural way with a subgroup of $G$. Clearly, $G_0 \cup U$ is the set of irreducible elements of $S$, and therefore $G_1$ is the set of all classes containing irreducible elements of $S$. Theorem 2 implies $\mu_m(B) \leq \mu_m(S)D(G_1)$, and Proposition 3 implies $\mu_m(S) = \mu_m(T)$.

ii) We may assume that $D(G_1) < \infty$, and we must prove that $n \in \mathbb{N}$, $u_1, \ldots, u_m, v_1, \ldots, v_n \in U$ and $u_1 \cdot \ldots u_m = v_1 \cdot \ldots v_n$ implies $n \leq \mu_m(B)D(G_1)$. Let $n \in \mathbb{N}$ and $u_1, \ldots, u_m, v_1, \ldots, v_n \in U$ be given, and $u_1 \cdot \ldots u_m = v_1 \cdot \ldots v_n$. We may suppose that there exists some $l \in \{0, \ldots, m\}$ such that $u_1, \ldots, u_l \notin B$ and $u_{l+1}, \ldots, u_m \in B$. For $1 \leq j \leq l$, $\iota(u_j) \in \iota(U) \subset [-G_0]$ implies the existence of $g_{j,1}, \ldots, g_{j,d_j} \in G_0$ such that

$$\iota(u_j) + \sum_{\nu=1}^{d_j} g_{j,\nu} = 0.$$
and we may assume that $d_j \in \mathbb{N}$ is minimal with this property. If $b_j = g_{j,1} \cdot \cdots \cdot g_{j,d_j} \in \mathcal{F}(G_0)$, then the element $b_j u_j \in B$ is irreducible (since $d_j$ is minimal), and

$$(b_1 u_1) \cdot \cdots \cdot (b_l u_l) u_{l+1} \cdot \cdots \cdot u_m = v_1 \cdot \cdots \cdot v_n b_1 \cdot \cdots \cdot b_l.$$  

The zero sum

$$0 = \sum_{\nu=1}^{n} \mu(v_\nu) + \sum_{j=1}^{l} \sum_{\nu=1}^{d_j} g_{j,\nu}$$

of elements of $G_1$ splits into $k \geq 0$ zero subsums each of which has at most $D(G_1)$ summands; This implies

$$v_1 \cdot \cdots \cdot v_n b_1 \cdot \cdots \cdot b_l = w_1 \cdot \cdots \cdot w_k,$$

where $w_i \in B$ and $kD(G_1) \geq n + d_1 + \cdots + d_l \geq n$. Factoring each $w_i$ into irreducible elements of $B$, we obtain

$$(b_1 u_1) \cdot \cdots \cdot (b_l u_l) u_{l+1} \cdot \cdots \cdot u_m = y_1 \cdot \cdots \cdot y_r,$$

where $y_i \in B$ are irreducible and $r \geq k$. This implies

$$\mu_m(B) \geq r \geq k \geq \frac{n}{D(G_1)},$$

whence the assertion. \( \square \)

§ 4 FINITELY PRIMARY MONOIDS

DEFINITION. A monoid $T$ is called finitely primary of rank $s \in \mathbb{N}$ and of exponent $\alpha \in \mathbb{N}$, if it is a submonoid of a factorial monoid $F$ containing exactly $s$ mutually non-associated prime elements $p_1, \ldots, p_s$,

$$T \subset F = \{p_1, \ldots, p_s\} \times F^\times,$$

satisfying the following two conditions:

1. $T^\times = T \cap F^\times$.

2. For any $a = p_1^{\alpha_1} \cdot \cdots \cdot p_s^{\alpha_s} u \in F$ (where $\alpha_1, \ldots, \alpha_s \in \mathbb{N}_0$ and $u \in F^\times$), the following two assertions hold true:

2a) If $a \in T \setminus T^\times$, then $\alpha_1 \geq 1, \ldots, \alpha_s \geq 1$.

2b) If $\alpha_1 \geq \alpha, \ldots, \alpha_s \geq \alpha$, then $a \in T$. 
The simplest examples of finitely primary monoids are finitely generated submonoids of \((\mathbb{N}_0, +)\). Indeed, if \(T = [d_1, \ldots, d_m] \subseteq \mathbb{N}_0\) and \(d = \gcd(d_1, \ldots, d_m)\), then there exists some \(\alpha \in \mathbb{N}\) such that \(d\alpha + d\mathbb{N}_0 \subseteq T\); we set \(F = d\mathbb{N}_0\) and see that \(T\) is finitely primary of rank 1 and exponent \(\alpha\).

Every finitely primary monoid is atomic, and it is primary in the sense of [15]. Our interest in finitely primary monoids comes from their appearance in the theory of one-dimensional domains, which is shown by the following proposition.

**Proposition 6.** Let \(R\) be a one-dimensional local noetherian domain such that its integral closure \(\bar{R}\) is a finitely generated \(R\)-module. If \(\max(\bar{R}) = \{p_1, \ldots, p_s\}\) and \([R : \bar{R}] = p_1^{\beta_1} \cdots p_s^{\beta_s}\), then \(R^*\) is finitely primary of rank \(s\) and of exponent \(\beta = \max\{\beta_1, \ldots, \beta_s\}\).

**Proof.** Being a semilocal Dedekind domain, \(\bar{R}\) is principal; if \(\max(\bar{R}) = \{p_1, \ldots, p_s\}\), then
\[\bar{R}^* = [p_1, \ldots, p_s] \times \bar{R}^x,
\]
where \(p_i = p_i\bar{R}\), and \(p_i \cap R\) is the maximal ideal of \(R\). Since \(\bar{R} \supset R\) is integral, we also have \(\bar{R}^x \cap R = R^x\).

Now let \(a = p_1^{\alpha_1} \cdots p_s^{\alpha_s} u \in \bar{R}^*\) be given, where \(\alpha_1, \ldots, \alpha_s \in \mathbb{N}_0\) and \(u \in \bar{R}^x\). If \(a \in R\), then either \(\alpha_1 = \cdots = \alpha_s = 0\) or \(\alpha_1 \geq 1, \ldots, \alpha_s \geq 1\); if \(\alpha_1 \geq \beta, \ldots, \alpha_s \geq \beta\) then \(aR \subseteq [R : \bar{R}] \subseteq R\) and hence \(a \in R\). \(\square\)

**Theorem 4.** Let \(T\) be a finitely primary monoid of rank \(s\) and exponent \(\alpha\), and suppose that \(T \subseteq F = [p_1, \ldots, p_s] \times F^x\) as in the definition.

\[\begin{array}{ll}
\text{i)} & T/F^x \text{ is finitely generated if and only if } s = 1 \text{ and } (F^x : T^x) < \infty. \\
\text{ii)} & \text{If } s = 1, \text{ then } \mu_m(T) \leq (2\alpha - 1)m \text{ for all } m \in \mathbb{N}, \text{ and } \rho(T) \leq 2\alpha - 1.
\end{array}\]

\[\begin{array}{ll}
\text{iii)} & \text{If } s \geq 2, \text{ then } \mu_m(T) = \infty \text{ for every } m \geq 2\alpha, \text{ and } \rho(T) = \infty.
\end{array}\]

**Proof.** Assume first that \(s \geq 2\). For \(n \in \mathbb{N}\), we consider the sets
\[T_n = \{z \in T \mid z = p_1^{\alpha_1} \cdots p_s^{\alpha_s} u, \ \alpha_1 \geq n, \ \alpha_2 \leq \alpha, \ldots, \alpha_s \leq \alpha, \ u \in F^x\}\,
\]
\[T'_n = \{z \in T \mid z = p_1^{\alpha_1} \cdots p_s^{\alpha_s} u, \ \alpha_1 \leq \alpha, \ \alpha_2 \geq n, \ldots, \alpha_s \geq n, \ u \in F^x\}\.
\]
For every \(z \in T_n \cup T'_n\), we have \(T(z) \leq \alpha\). If \(z \in T\) and \(z' \in T\), then
\[zz' = p_1^{\alpha_1} \cdots p_s^{\alpha_s} u\,\]
where $\alpha_1, \ldots, \alpha_s \geq n+1$ and $u \in F^\times$. Since $p_1^{\beta_1} \cdots p_s^{\beta_s} v \in T$ whenever $\beta_1 \geq \alpha, \ldots, \beta_s \geq \alpha$ and $v \in F^\times$, the element $zz'$ factors in $T$ in the form

$$zz' = [(p_1 \cdots p_s)^{\alpha}] t \cdot [p_1^{\alpha_1-\alpha} \cdots p_s^{\alpha_s-\alpha}],$$

where $t = \lfloor \frac{n+1}{\alpha} \rfloor - 1$; this implies

$$L^T(zz') \geq \left\lfloor \frac{n+1}{\alpha} \right\rfloor .$$

On the other hand,

$$l^T(zz') \leq l^T(z) + l^T(z') \leq 2\alpha ,$$

and therefore $\mu_m(T) \geq \left\lfloor \frac{n+1}{\alpha} \right\rfloor$, whenever $m \geq 2\alpha$. Since $n$ was arbitrary, we obtain $\mu_m(T) = \infty$ if $m \geq 2\alpha$, and consequently also $\rho(T) = \infty$. By Theorem 1, $T/T^\times$ is not finitely generated.

Now we assume $s = 1$. The irreducible elements of $T$ are of the form $p^\gamma w$, where $1 \leq \gamma \leq 2\alpha - 1$ and $w \in T^\times$. If $z \in T \setminus T^\times$, $z = p^\beta u$, where $\beta \in \mathbb{N}$ and $u \in T^\times$, then

$$L^T(z) \leq \beta , \quad l^T(z) \geq \frac{\beta}{2\alpha - 1}$$

and hence $L^T(z) \leq (2\alpha - 1)l^T(z)$, which implies $\mu_m(T) \leq (2\alpha - 1)m$ for all $m \in \mathbb{N}$ and $\rho(T) \leq 2\alpha - 1$.

Let $(u_i)_{i \in I}$ be a set of representatives of $F^\times/T^\times$; then the set

$$T_0 = \{ p_1^{\beta} u_i T^\times \in T/T^\times \mid 1 \leq \beta \leq \alpha, \ i \in I \}$$

generates $T/T^\times$. If $(F^\times : T^\times) = \#I < \infty$, then $T_0$ is finite and hence $T/T^\times$ is finitely generated. If $(F^\times : T^\times) = \#I = \infty$, then $T_0$ contains infinitely many irreducible elements, and therefore $T/T^\times$ is not finitely generated. \(\Box\)

**Remark.** In the context of one-dimensional (noetherian) domains, parts of Theorem 4 are proved in [4; Theorem 2.12].
§ 5 ONE-DIMENSIONAL DOMAINS

We start with some finiteness conditions for one-dimensional local domains.

**Proposition 7.** Let $R$ be a one-dimensional local noetherian domain with maximal ideal $p$ and $\bar{R}$ its integral closure. Suppose that $\bar{R}$ is a finitely generated $R$-module, $\bar{R} \neq R$, and that $\bar{R}$ is also local, with maximal ideal $\bar{p}$. Then the following conditions are equivalent:

- a) $(\bar{R}^\times : R^\times) < \infty$.
- b) $(R : p) < \infty$.
- c) $(\bar{R} : \bar{p}) < \infty$.

**Proof.** We set $k = R/p$, $\bar{k} = \bar{R}/\bar{p}$, and we view $k$ as a subfield of $\bar{k}$. Since $\bar{R}$ is a finitely generated $R$-module, we obtain $[\bar{k} : k] < \infty$; therefore b) and c) are equivalent.

For the following, recall that there are (canonical) isomorphisms $\bar{R}^\times/(1 + \bar{p}) \simeq \bar{k}^\times$ and $(1 + \bar{p}^a)/(1 + \bar{p}^{a+1}) \simeq \bar{k}$ for any $a \geq 1$; see [6; ch. 1, Prop. 4].

- c) $\implies$ a): If $[R : \bar{R}] = \bar{p}^e$ is the conductor of $\bar{R}$, then $1 + \bar{p}^e \subset R^\times$, and consequently there is an epimorphism

$$\bar{R}^\times/(1 + \bar{p}^e) \twoheadrightarrow \bar{R}^\times/R^\times.$$ 

Since $\bar{k}$ is finite, the same is true for $\bar{R}^\times/(1 + \bar{p}^e)$ and hence for $\bar{R}^\times/R^\times$.

- a) $\implies$ c): The canonical mapping $\bar{R} \to \bar{k}$ induces an epimorphism $\bar{R}^\times/R^\times \twoheadrightarrow \bar{k}^\times/k^\times$, showing that $\bar{k}^\times/k^\times$ is finite. If $\bar{k} \neq k$, this implies that both, $k$ and $\bar{k}$, are finite. If $\bar{k} = k$, then $R + \bar{p} = \bar{R}$; by Nakayama's Lemma, we have $R + p\bar{R} \neq \bar{R}$ and hence $p\bar{R} = \bar{p}^e$ for some $e \geq 2$. Since $\bar{R} = R + \bar{p}$, we obtain $\bar{R}^\times = R^\times(1 + \bar{p})$, and therefore

$$\bar{R}^\times/R^\times \simeq (1 + \bar{p})/(1 + \bar{p}) \cap R^\times = (1 + \bar{p})/(1 + p).$$

is finite. But $1 + p \subset 1 + p\bar{R} = 1 + \bar{p}^e \subset 1 + \bar{p}$, and consequently $(1 + \bar{p})/(1 + \bar{p}^e)$ is also finite, which implies that $\bar{k}$ is finite. \qed

**Theorem 5.** Let $R$ be a one-dimensional noetherian domain with class group $G = \text{Pic}(R)$. Suppose that the integral closure $\bar{R}$ of $R$ is a finitely generated $R$-module, and let $\mathfrak{F} = [R : \bar{R}]$ be the conductor of $\bar{R}$. Let $p_1, \ldots, p_m \in \text{max}(R)$ be the prime ideals of $R$ lying above $\mathfrak{F}$, and set

$$\rho^*(R) = \max\{\rho(R_{p_j}) \mid 1 \leq j \leq m\}.$$
Let $G_0$ be the set of all classes $g \in G$ containing some prime ideal $p \in \text{max}(R)$ different from $p_1, \ldots, p_m$.

i) We have the estimate
\[ \rho(B(G_0)) \leq \rho(R) \leq D(G)\rho^*(R). \]

ii) If $G = [G_0]$, then
\[ \rho^*(R) \leq \rho(R)D(G). \]

iii) Suppose that $G = [G_0]$; then we have $\rho^*(R) < \infty$ if and only if, for each $j \in \{1, \ldots, m\}$, there is exactly one prime ideal $\bar{p}_j$ of $\bar{R}$ lying above $p_j$; if this is the case and $\mathcal{G} = \bar{p}_1^{\alpha_1} \cdots \bar{p}_m^{\alpha_m}$ then
\[ \rho^*(R) \leq 2 \max\{\alpha_1, \ldots, \alpha_m\} - 1. \]

iv) Suppose that $\rho^*(R) < \infty$, $G_0$ is finite and $(R : p_j) < \infty$ for $1 \leq j \leq m$. Then $R$ has accepted elasticity.

Proof. Let
\[ \bar{\varphi} : R^* \longrightarrow \coprod_{p \in \text{max}(R)} R^*_p / R^*_p \]
be the divisor homomorphism associated with the finite character representation
\[ R = \bigcap_{p \in \text{max}(R)} R_p. \]

We set $P = \text{max}(R) \setminus \{p_1, \ldots, p_m\}$, $T_j = R^*_p / R^*_p$ and $T = T_1 \times \cdots \times T_m$. If $p \in P$, then $R_p$ is a discrete valuation ring, and we denote by $\pi_p \in R_p$ a prime element. The mapping
\[ \psi : \begin{cases} \mathcal{F}(P) \rightarrow \coprod_{p \in P} R^*_p / R^*_p \\
\prod_{p \in P} p^{n_p} \mapsto (\pi_p^{n_p} R^*_p)_{p \in P} \end{cases} \]
is an isomorphism, and
\[ \varphi : R^* \xrightarrow{\bar{\varphi}} \coprod_{p \in \text{max}(R)} R^*_p / R^*_p \xrightarrow{\psi^{-1} \times \text{id}} \mathcal{F}(P) \times T \]
is a divisor homomorphism whose class group coincides with the class group of $R$. If $\iota : \mathcal{F}(P) \times T \rightarrow G$ is the canonical homomorphism, then $\iota(P) = G_0$. By Proposition 5,
\[ \rho(R) = \rho(B(G_0, T, \iota)). \]
and if $G_0$ is finite and $T$ is finitely generated, then $R$ has accepted elasticity. Now i) and ii) follow from Theorem 3, since
\[
\rho(T) = \max\{\rho(T_j) \mid 1 \leq j \leq m\} = \max\{\rho(R_{p_j}) \mid 1 \leq j \leq m\} = \rho^*(R)
\]
by Proposition 4.

For $j \in \{1, \ldots, m\}$, let $s_j$ be the number of prime ideals of $\bar{R}$ lying above $p_j$, and let $\bar{R}_{p_j}$ be the integral closure of $R_{p_j}$; then $\# \max(\bar{R}_{p_j}) = s_j$ and, by Proposition 6 $R_{p_j}^*$ is finitely primary of rank $s_j$. If $s_j \geq 2$ for some $j \in \{1, \ldots, m\}$, then $\rho(R_{p_j}^*) = \infty$ by Theorem 4 and consequently $\rho^*(R) = \infty$. If $s_j = 1$, then $[R_{p_j} : \bar{R}_{p_j}] = [R : \bar{R}] \bar{R}_{p_j} = (\bar{p}_j \bar{R}_{p_j})^{\alpha_j}$, and Theorem 4 implies $\rho(R_{p_j}^*) \leq 2\alpha_j - 1$, whence $\rho^*(R) \leq 2\max\{\alpha_1, \ldots, \alpha_m\} - 1$.

It remains to prove iv). We suppose that $s_1 = \cdots = s_m = 1$ and that $(R : p_j) < \infty$ for $1 \leq j \leq m$. Then we obtain $(R_{p_j} : p_j) = (R : p_j) < \infty$ and hence
\[
(R_{p_j}^* : R_{p_j}^*) < \infty
\]
by Proposition 7. Hence all $T_j$ are finitely generated by Theorem 4. Consequently, $T$ is finitely generated and $R$ has accepted elasticity by Proposition 5.

**COROLLARY 4.** Let $R$ be an order in an algebraic number field and $\bar{R}$ its integral closure.

i) If for some prime ideal $p$ of $R$ there is more than one prime ideal of $\bar{R}$ lying above $p$, then $\rho(R) = \infty$.

ii) If for every prime ideal $p$ of $R$ there is exactly one prime ideal of $\bar{R}$ lying above $p$, then $R$ has accepted elasticity.

**Proof.** If $R$ is an order in an algebraic number field, then its class group is finite and every class contains infinitely many prime ideals; $\bar{R}$ is a finitely generated $R$-module, and all residue fields are finite. Now the assertion follows from Theorem 5.

**EXAMPLE.** We consider the ring $R = \mathbb{Z}[3i]$ $(i = \sqrt{-1})$. Then we have $\bar{R} = \mathbb{Z}[i]$, $[R : \bar{R}] = 3R$, and the class group of $R$ is of order 2. Theorem 5 implies $\rho^*(R) = 1$, and consequently $\rho(R) \leq 2$. The conjecture stated on p. 231 in [1] would imply $\rho(R) = 1$, but this is not the case.

If $\beta = 1 + 2i$, $\beta' = 1 - 2i$, then $3\beta$, $3\beta'$, 3 and 5 are irreducible elements of $R$ satisfying $(3\beta)(3\beta') = 3^2 \cdot 5$. In fact, it is not difficult to see that $\rho(R) = \frac{3}{2}$.
