# Computation of 2-groups of positive classes of exceptional number fields 

par Jean-François JaULENT, Sebastian PaULI, Michael E. POHST et Florence SORIANO-GAFIUK

#### Abstract

RÉSumÉ. Nous développons un algorithme pour déterminer le 2 -groupe $\mathcal{C} \ell_{F}^{\text {pos }}$ des classes positives dans le cas où le corps de nombres considéré $F$ possède des places paires exceptionnelles. Cela donne en particulier le 2-rang du noyau sauvage $W K_{2}(F)$.

Abstract. We present an algorithm for computing the 2-group $\mathcal{C} \ell_{F}^{\text {pos }}$ of the positive divisor classes in case the number field $F$ has exceptional dyadic places. As an application, we compute the 2-rank of the wild kernel $W K_{2}(F)$ in $K_{2}(F)$.

## 1. Introduction

The logarithmic $\ell$-class group $\widetilde{\mathcal{C} \ell}_{F}$ was introduced in [10] by J.-F. Jaulent who used it to study the $\ell$-part $W K_{2}(F)$ of the wild kernel in number fields: if $F$ contains a primitive $2 \ell^{t}$-th root of unity $(t>0)$, there is a natural isomorphism

$$
\mu_{\ell^{t}} \otimes_{\mathbb{Z}} \widetilde{\mathcal{C} \ell_{F}} \simeq W K_{2}(F) / W K_{2}(F)^{\ell^{t}}
$$

so the $\ell$-rank of $W K_{2}(F)$ coincides with the $\ell$-rank of the logarithmic group $\widetilde{\mathcal{C} \ell}{ }_{F}$. An algorithm for computing $\widetilde{\mathcal{C} \ell}$ F for Galois extensions $F$ was developed in [4] and later generalized and improved for arbitrary number fields in [3].

In case the prime $\ell$ is odd, the assumption $\mu_{\ell} \subset F$ may be easily passed if one considers the cyclotomic extension $F\left(\mu_{\ell}\right)$ and gets back to $F$ via the so-called transfer (see [12], [15] and [17]). However for $\ell=2$ the connection between symbols and logarithmic classes is more intricate: in the non-exceptional situation (i.e. when the cyclotomic $\mathbb{Z}_{2}$-extension $F^{c}$ contains the fourth root of unity $i$ ) the 2-rank of $W K_{2}(F)$ still coincides with the 2 -rank of $\widetilde{\mathcal{C}}_{F}$. Even more if the number field $F$ has no exceptional dyadic place (i.e. if one has $i \in F_{\mathfrak{q}}^{c}$ for any $\mathfrak{q} \mid 2$ ), the same result holds if one replaces the ordinary logarithmic class group ${\widetilde{\mathcal{C}} \ell_{F}}$ by a narrow version $\widetilde{\mathcal{C}}{ }_{F}^{\text {res }}$. The algorithmic aspect of this is treated in [11].

Manuscrit reçu le 9 janvier 2008.

Last in [13] the authors pass the difficulty in the remaining case by introducing a new 2 -class group $\mathcal{C} \ell_{F}^{\text {pos }}$, the 2-group of positive divisor classes, which satisfies the rank identity: $\mathrm{rk}_{2} \mathcal{C} \ell_{F}^{\text {pos }}=\mathrm{rk}_{2} W K_{2}(F)$.

In this paper we develop an algorithm for computing both $\mathcal{C} \ell_{F}^{p o s}$ and $\widetilde{\mathcal{C}} \ell_{F}^{p o s}$ in case the number field $F$ does contain exceptional dyadic places.

We conclude with several examples. Combining our algorithm with the work of Belabas and Gangl [1] on the computation of the tame kernel of $K_{2}$ we obtain the complete structure of the wild kernel in some cases.

## 2. Positive divisor classes of degree zero

### 2.1. The group of logarithmic divisor classes of degree zero.

Throughout this paper the prime number $\ell$ equals 2 and we let $i$ be a primitive fourth root of unity. Let $F$ be a number field of degree $n=r+2 c$. According to [9], for every place $\mathfrak{p}$ of $F$ there exists a 2 -adic valuation $\widetilde{v}_{\mathfrak{p}}$ which is related to the wild 2 -symbol in case the cyclotomic $\mathbb{Z}_{2}$-extension of $F_{\mathfrak{p}}$ contains $i$. The degree $\operatorname{deg} \mathfrak{p}$ of $\mathfrak{p}$ is a 2 -adic integer such that the image of the map $\log \left|\left.\right|_{\mathfrak{p}}\right.$ is the $\mathbb{Z}_{2}$-module $\operatorname{deg}(\mathfrak{p}) \mathbb{Z}_{2}$ (see [10]). (By Log we mean the usual 2 -adic logarithm.) The construction of the 2-adic logarithmic valuations $\widetilde{v}_{\mathfrak{p}}$ yields

$$
\begin{equation*}
\forall \alpha \in \mathcal{R}_{F}:=\mathbb{Z}_{2} \otimes_{\mathbb{Z}} F^{\times}: \sum_{\mathfrak{p} \in P l_{F}^{0}} \widetilde{v}_{\mathfrak{p}}(\alpha) \operatorname{deg}(\mathfrak{p})=0 \tag{1}
\end{equation*}
$$

where $P l_{F}^{0}$ denotes the set of finite places of the number field $F$. Setting

$$
\widetilde{\operatorname{div}}(\alpha):=\sum_{\mathfrak{p} \in P l_{F}^{0}} \widetilde{v}_{\mathfrak{p}}(\alpha) \mathfrak{p}
$$

we obtain by $\mathbb{Z}_{2}$-linearity:

$$
\begin{equation*}
\operatorname{deg}(\widetilde{\operatorname{div}}(\alpha))=0 \tag{2}
\end{equation*}
$$

We define the 2-group of logarithmic divisors of degree 0 as the kernel of the degree map deg in the direct sum $\mathcal{D} \ell_{F}=\sum_{\mathfrak{p} \in P l_{F}^{0}} \mathbb{Z}_{2} \mathfrak{p}$ :

$$
\widetilde{\mathcal{D} \ell}{ }_{F}:=\left\{\sum_{\mathfrak{p} \in P l_{F}^{0}} a_{\mathfrak{p}} \mathfrak{p} \in \mathcal{D} \ell_{F} \mid \sum_{\mathfrak{p} \in P l_{F}^{0}} a_{\mathfrak{p}} \operatorname{deg}(\mathfrak{p})=0\right\}
$$

and the subgroup of principal logarithmic divisors as the image of the logarithmical map div:

$$
\widetilde{\mathcal{P} \ell_{F}}:=\left\{\widetilde{\operatorname{div}}(\alpha) \mid \alpha \in \mathcal{R}_{F}\right\}
$$

Because of (2) $\widetilde{\mathcal{P} \ell}_{F}$ is clearly a subgroup of $\widetilde{\mathcal{D} \ell}{ }_{F}$. Moreover by the so-called generalised Gross conjecture, the factorgroup

$$
{\widetilde{\mathcal{C}} \ell_{F}}:={\widetilde{\mathcal{D} \ell} \ell_{F}} /{\widetilde{\mathcal{P}} \ell_{F}}
$$

is a finite 2-group, the 2-group of logarithmic divisor classes. So, under this conjecture, $\widetilde{\mathcal{C} \ell}{ }_{F}$ is just the torsion subgroup of the group

$$
\mathcal{C} \ell_{F}:=\mathcal{D} \ell_{F} / \widetilde{\mathcal{P} \ell_{F}}
$$

of logarithmic classes (without any assumption of degree).
Remark 1. Let $F^{+}$be the set of all totally positive elements of $F^{\times}$(i.e. the subgroup $F^{+}:=\left\{x \in F^{\times} \mid x_{\mathfrak{p}}>0 \quad\right.$ for all real $\left.\left.\mathfrak{p}\right\}\right)$. For

$$
\widetilde{\mathcal{P} \ell_{F}^{+}}:=\left\{\widetilde{\operatorname{div}}(\alpha) \mid \alpha \in \mathcal{R}_{F}^{+}:=\mathbb{Z}_{2} \otimes_{\mathbb{Z}} F^{+}\right\}
$$

the factor group

$$
\left.\mathcal{C} \ell_{F}^{\text {res }}:=\mathcal{D} \ell_{F} / \widetilde{\mathcal{P} \ell}{ }_{F}^{+} \quad \text { (resp. }{\widetilde{\mathcal{C}} \ell_{F}^{r e s}}_{\text {res }}^{\mathcal{D} \ell} / \widetilde{\mathcal{P} \ell}{ }_{F}^{+}\right)
$$

is the 2-group of narrow logarithmic divisor classes of the number field $F$ (resp. the 2-group of narrow logarithmic divisor classes of degree 0) introduced in [16] and computed in [11].
2.2. Signs and places. For a field $F$ we denote by $F^{c}$, (respectively $\left.F^{c}[i]\right)$ the cyclotomic $\mathbb{Z}_{2}$-extension (resp. the maximal cyclotomic pro-2-extension) of $F$.

We adopt the notations and definitions in this section from [13].
Definition 1 (signed places). Let $F$ be a number field. We say that a non-complex place $\mathfrak{p}$ of $F$ is signed if and only if $F_{\mathfrak{p}}$ does not contain the fourth root of unity $i$. These are the places which do not decompose in the extension $F[i] / F$.

We say that $\mathfrak{p}$ is logarithmically signed if and only if the cyclotomic $\mathbb{Z}_{2}$-extension $F_{\mathfrak{p}}^{c}$ does not contain $i$. These are the places which do not decompose in $F^{c}[i] / F^{c}$.

Definition 2 (sets of signed places). By $P S$, respectively $P L S$, we denote the sets of signed, respectively logarithmically signed, places:

$$
\begin{aligned}
P S & :=\left\{\mathfrak{p} \mid i \notin F_{\mathfrak{p}}\right\}, \\
P L S & :=\left\{\mathfrak{p} \mid i \notin F_{\mathfrak{p}}^{c}\right\} .
\end{aligned}
$$

A finite place $\mathfrak{p} \in P L S$ is called exceptional. The set of exceptional places is denoted by PE. Exceptional places are even (i.e. finite places dividing 2).

These sets satisfy the following inclusions:

$$
P S \subset P L S=P E \cup P R \subset P l(2) \cup P l(\infty)
$$

where $P l(2), P l(\infty), P R$ denote the sets of even, infinite and real places of $F$, respectively. From this the finiteness of $P L S$ is obvious.

We recall the canonical decomposition $\mathbb{Q}_{2}^{\times}=2^{\mathbb{Z}} \times\left(1+4 \mathbb{Z}_{2}\right) \times\langle-1\rangle$ and we denote by $\epsilon$ the projection from $\mathbb{Q}_{2}^{\times}$onto $\langle-1\rangle$.

Definition 3 (sign function). For all places $\mathfrak{p}$ we define a sign function via

$$
\operatorname{sg}_{\mathfrak{p}}: F_{\mathfrak{p}}^{\times} \rightarrow\langle-1\rangle: x \mapsto \begin{cases}1 & \text { for } \mathfrak{p} \text { complex } \\ \operatorname{sign}(x) & \text { for } \mathfrak{p} \text { real } \\ \epsilon\left(N_{\mathfrak{p}}^{-\nu_{\mathfrak{p}}(x)}\right) & \text { for } \mathfrak{p} \nmid 2 \infty \\ \epsilon\left(N_{F_{\mathfrak{p}} / \mathbb{Q}_{2}}(x) N \mathfrak{p}^{-\nu_{\mathfrak{p}}(x)}\right) & \text { for } \mathfrak{p} \mid 2\end{cases}
$$

These sign functions satisfy the product formula:

$$
\forall x \in F^{\times} \quad \prod_{\mathfrak{p} \in P l_{F}} \operatorname{sg}_{\mathfrak{p}}(x)=1
$$

In addition we have:
Proposition 1. The places $\mathfrak{p}$ of $F$ satisfy the following properties:
(i) if $\mathfrak{p} \in P L S$ then $\left(\operatorname{sg}_{\mathfrak{p}}, \widetilde{v}_{\mathfrak{p}}\right)$ is surjective;
(ii) if $\mathfrak{p} \in P S \backslash P L S$ then $\operatorname{sg}_{\mathfrak{p}}()=(-1)^{\widetilde{v}_{\mathfrak{p}}}()$ and $\widetilde{v}_{\mathfrak{p}}$ is surjective;
(iii) if $\mathfrak{p} \notin P S$ then $\operatorname{sg}_{\mathfrak{p}}\left(F_{\mathfrak{p}}^{\times}\right)=1$ and $\widetilde{v}_{\mathfrak{p}}$ is surjective.

Remark 2. The logarithmic valuation $\widetilde{v}_{\mathfrak{p}}$ is surjective in all three cases. Part 2 of the preceding result is often used for testing $\mathfrak{p} \in P L S$.
2.3. The group of positive divisor classes. For the introduction of that group we modify several notations from [13] in order to make them suitable for actual computations.

Since $P L S$ is finite we can fix the order of the logarithmically signed places, say $P L S=\left\{\mathfrak{p}_{1}, \ldots, \mathfrak{p}_{m}\right\}$, with $P E=\left\{\mathfrak{p}_{1}, \ldots, \mathfrak{p}_{e}\right\}$ and $P R=$ $\left\{\mathfrak{p}_{e+1}, \ldots, \mathfrak{p}_{m}\right\}$. Accordingly we define vectors $\mathbf{e}=\left(e_{1}, \ldots, e_{m}\right) \in\{ \pm 1\}^{m}$.

For each divisor $\mathfrak{a}=\sum_{\mathfrak{p} \in P l_{F}^{0}} a_{\mathfrak{p}} \mathfrak{p}$, we form pairs ( $\left.\mathfrak{a}, \mathbf{e}\right)$ and put

$$
\begin{equation*}
\operatorname{sg}(\mathfrak{a}, \mathbf{e}):=\prod_{\mathfrak{p} \in P S \backslash P L S}(-1)^{a_{\mathfrak{p}}} \times \prod_{i=1}^{m} e_{i} \tag{3}
\end{equation*}
$$

Let $\mathcal{D} \ell_{F}(P E):=\left\{\mathfrak{a} \in \mathcal{D} \ell_{F} \mid \mathfrak{a}=\sum_{\mathfrak{p} \in P E} a_{\mathfrak{p}} \mathfrak{p}\right\}$ be the $\mathbb{Z}_{2}$-submodule of $\mathcal{D} \ell_{F}$ generated by the exceptional dyadic places. And let $\mathcal{D} \ell_{F}^{P E}$ be the factor group $\mathcal{D} \ell_{F} / \mathcal{D} \ell_{F}(P E)$. Thus the group of positive divisors is the $\mathbb{Z}_{2}$-module:

$$
\begin{equation*}
\mathcal{D} \ell_{F}^{\text {pos }}:=\left\{(\mathfrak{a}, \mathbf{e}) \in \mathcal{D} \ell_{F}^{P E} \times\{ \pm 1\}^{m} \mid \operatorname{sg}(\mathfrak{a}, \mathbf{e})=1\right\} \tag{4}
\end{equation*}
$$

For $\alpha \in \mathcal{R}_{F}:=\mathbb{Z}_{2} \otimes_{\mathbb{Z}} F^{\times}$, let $\widetilde{\operatorname{div}^{\prime}}(\alpha)$ denote the image of $\widetilde{\operatorname{div}}(\alpha)$ in $\mathcal{D} \ell_{F}^{P E}$ and $\operatorname{sg}(\alpha)$ the vector of signs $\left(\operatorname{sg}_{\mathfrak{p}_{1}}(\alpha), \ldots, \operatorname{sg}_{\mathfrak{p}_{m}}(\alpha)\right)$ in $\{ \pm 1\}^{m}$. Then

$$
\begin{equation*}
\left.\widetilde{\mathcal{P}} \ell_{F}^{p o s}:=\left\{\widetilde{\operatorname{div}^{\prime}}(\alpha), \operatorname{sg}(\alpha)\right) \in \mathcal{D} \ell_{F}^{P E} \times\{ \pm 1\}^{m} \mid \alpha \in \mathcal{R}_{F}\right\} \tag{5}
\end{equation*}
$$

is obviously a submodule of $\mathcal{D} \ell_{F}^{\text {pos }}$ which is called the principal submodule.

Definition 4 (positive divisor classes). With the notations above:
(i) The group of positive logarithmic divisor classes is the factor group

$$
\mathcal{C} \ell_{F}^{\text {pos }}=\mathcal{D} \ell_{F}^{\text {pos }} / \widetilde{\mathcal{P} \ell}{ }_{F}^{\text {pos }}
$$

(ii) The subgroup of positive logarithmic divisor classes of degree zero is the kernel $\widetilde{\mathcal{C} \ell}{ }_{F}^{\text {pos }}$ of the degree map deg in $\mathcal{C} \ell_{F}^{\text {pos }}$ :

$$
\widetilde{\mathcal{C} \ell}{ }_{F}^{p o s}:=\left\{(\mathfrak{a}, \mathbf{e})+\widetilde{\mathcal{P} \ell}{ }_{F}^{p o s} \mid \operatorname{deg}(\mathfrak{a}) \in \operatorname{deg}\left(\mathcal{D} \ell_{F}(P E)\right)\right\}
$$

Remark 3. The group $\mathcal{C} \ell_{F}^{\text {pos }}$ is infinite whenever the number field $F$ has no exceptional places, since in this case $\operatorname{deg}\left(\mathcal{C} \ell_{F}^{\text {pos }}\right)$ is isomorphic to $\mathbb{Z}_{2}$. The finiteness of $\mathcal{C} \ell_{F}^{\text {pos }}$ in case $P E \neq \emptyset$ follows from the so-called generalized Gross conjecture.

For the computation of $\widetilde{\mathcal{C} \ell}{ }_{F}^{\text {pos }}$ we need to introduce primitive divisors.
Definition 5. A divisor $\mathfrak{b}$ of $F$ is called a primitive divisor if $\operatorname{deg}(\mathfrak{b})$ generates the $\mathbb{Z}_{2}$-module $\operatorname{deg}\left(\mathcal{D} \ell_{F}\right)=4\left[F \cap \mathbb{Q}^{c}: \mathbb{Q}\right] \mathbb{Z}_{2}$.

We close this section by presenting a method for exhibiting such a divisor:
Let $\mathfrak{q}_{1}, \ldots, \mathfrak{q}_{s}$ be all dyadic primes and $\mathfrak{p}_{1}, \ldots, \mathfrak{p}_{s}$ be a finite set of nondyadic primes which generates the 2 -group of 2 -ideal-classes $\mathcal{C} \ell_{F}^{\prime}$ (i.e. the quotient of the usual 2 -class group by the subgroup generated by ideals above 2).

Then every $\mathfrak{p} \in\left\{\mathfrak{q}_{1}, \ldots, \mathfrak{q}_{s}, \mathfrak{p}_{1}, \ldots, \mathfrak{p}_{t}\right\}$ with minimal 2-valuation $\nu_{2}(\operatorname{deg} \mathfrak{p})$ is primitive.
2.4. Galois interpretations and applications to $\boldsymbol{K}$-theory. Let $F^{l c}$ be the locally cyclototomic 2 -extension of $F$ (i.e. the maximal abelian pro-2extension of $F$ which is completely split at every place over the cyclotomic $\mathbb{Z}_{2}$-extension $F^{c}$ ). Then by $\ell$-adic class field theory ( $c f .[9]$ ), one has the following interpretations of the logarithmic class groups:

$$
\operatorname{Gal}\left(F^{l c} / F\right) \simeq \mathcal{C} \ell_{F} \quad \text { and } \quad \operatorname{Gal}\left(F^{l c} / F^{c}\right) \simeq \widetilde{\mathcal{C} \ell} F
$$

Remark 4. Let us assume $i \notin F^{c}$. Thus we may list the following special cases:
(i) In case $P L S=\emptyset$, the group $\mathcal{C} \ell_{F}^{\text {pos }} \simeq \mathbb{Z}_{2} \oplus \widetilde{\mathcal{C}} \ell_{F}^{\text {pos }}$ of positive divisor classes has index 2 in the group $\mathcal{C} \ell_{F} \simeq \mathbb{Z}_{2} \oplus \widetilde{\mathcal{C}} \ell_{F}$ of logarithmic classes of arbitrary degree; as a consequence its torsion subgroup $\widetilde{\mathcal{C}}{ }_{F}^{\text {pos }}$ has index 2 in the finite group ${\widetilde{\mathcal{C}} \ell_{F}}$ of logarithmic classes of degree 0 which was already computed in [3].
(ii) In case $P E=\emptyset$, the group $\mathcal{C} \ell_{F}^{\text {pos }} \simeq \mathbb{Z}_{2} \oplus \widetilde{\mathcal{C}} \ell_{F}^{\text {pos }}$ has index 2 in the group $\mathcal{C} \ell_{F}^{\text {res }} \simeq \mathbb{Z}_{2} \oplus \widetilde{\mathcal{C} \ell}{ }_{F}^{\text {res }}$ of narrow logarithmic classes of arbitrary degree; and its torsion subgroup $\widetilde{\mathcal{C} \ell}{ }_{F}^{\text {pos }}$ has index 2 in the finite group $\widetilde{\mathcal{C}} \ell_{F}^{\text {res }}$ of narrow logarithmic classes of degree 0 which was introduced in [16] and computed in [11].

Definition 6. We adopt the following conventions from $[6,7,13,14]$ :
(i) $F$ is exceptional whenever one has $i \notin F^{c}$ (i.e. $\left[F^{c}[i]: F^{c}\right]=2$ );
(ii) $F$ is logarithmically signed whenever one has $i \notin F^{l c}($ i.e. $P L S \neq \emptyset)$;
(iii) $F$ is primitive whenever at least one of the exceptional places does not split in (the first step of the cyclotomic $\mathbb{Z}_{2}$-extension) $F^{c} / F$.

The following theorem is a consequence of the results in $[6,7,9,10,13$, 14]:

Theorem 1. Let $W K_{2}(F)\left(r e s p . ~ K_{2}^{\infty}(F):=\cap_{n \geq 1} K_{2}^{2^{n}}(F)\right)$ be the 2-part of the wild kernel (resp. the 2-subgroup of infinite height elements) in $K_{2}(F)$.
(i) In case $i \in F^{l c}$ (i.e. in case $P L S=\emptyset$ ), we have both:

$$
\mathrm{rk}_{2} W K_{2}(F)=\mathrm{rk}_{2} \widetilde{\mathcal{C} \ell_{F}}=\mathrm{rk}_{2} \widetilde{\mathcal{C} \ell_{F}^{r e s}}
$$

(ii) In case $i \notin F^{l c}$ but $F$ has no exceptional places (i.e. $P E=\emptyset$ ), we have:

$$
\mathrm{rk}_{2} W K_{2}(F)=\mathrm{rk}_{2} \widetilde{\mathcal{C} \ell}{ }_{F}^{r e s}
$$

(iii) In case $P E \neq \emptyset$, then we have

$$
\mathrm{rk}_{2} W K_{2}(F)=\mathrm{rk}_{2} \mathcal{C} \ell_{F}^{\text {pos }}
$$

And in this last situation there are two subcases:
(a) If $F$ is primitive, i.e. if the set PE of exceptional dyadic places contains a primitive place, we have:

$$
K_{2}^{\infty}(F)=W K_{2}(F) .
$$

(b) If $F$ is imprimitive and $K_{2}^{\infty}(F)=\oplus_{i=1}^{n} \mathbb{Z} / 2^{n_{i}} \mathbb{Z}$, we get:
(i) $W K_{2}(F)=\mathbb{Z} / 2^{n_{1}+1} \mathbb{Z} \oplus\left(\oplus_{i=2}^{n} \mathbb{Z} / 2^{n_{i}} \mathbb{Z}\right)$ if $\mathrm{rk}_{2}\left(\widetilde{\mathcal{C} \ell}{ }_{F}^{\text {pos }}\right)=\mathrm{rk}_{2}\left(\mathcal{C} \ell_{F}^{\text {pos }}\right)$;
(ii) $W K_{2}(F)=\mathbb{Z} / 2 \mathbb{Z} \oplus\left(\oplus_{i=1}^{n} \mathbb{Z} / 2^{n_{i}} \mathbb{Z}\right)$ if $\mathrm{rk}_{2}\left(\widetilde{\mathcal{C} \ell}{ }_{F}^{\text {pos }}\right)<\operatorname{rk}_{2}\left(\mathcal{C} \ell_{F}^{\text {pos }}\right)$.

## 3. Computation of positive divisor classes

We assume in the following that the set $P E$ of exceptional places is not empty.
3.1. Computation of exceptional units. Classically the group of logarithmic units is the kernel in $\mathcal{R}_{F}$ of the logarithmic valuations (see [9]):

$$
\widetilde{\mathcal{E}}_{F}=\left\{x \in \mathcal{R}_{F} \mid \forall \mathfrak{p} \quad \widetilde{v}_{\mathfrak{p}}(x)=0\right\} .
$$

In order to compute positive divisor classes in case $P E$ is not empty, we introduce a new group of units:

Definition 7. We define the group of logarithmic exceptional units as the kernel of the non-exceptional logarithmic valuations:

$$
\begin{equation*}
\widetilde{\mathcal{E}}_{F}^{e x}=\left\{x \in \mathcal{R}_{F} \mid \forall \mathfrak{p} \notin P E \quad \widetilde{v}_{\mathfrak{p}}(x)=0\right\} . \tag{6}
\end{equation*}
$$

We only know that the group of logarithmic exceptional units is a subgroup of the 2-group of 2-units $\mathcal{E}_{F}^{\prime}=\mathbb{Z}_{2} \otimes E_{F}^{\prime}$. If we assume that there are exactly $s$ places in $F$ containing 2 we have, say:

$$
\mathcal{E}_{F}^{\prime}=\mu_{F} \times\left\langle\varepsilon_{1}, \ldots, \varepsilon_{r+c-1+s}\right\rangle .
$$

For the calculation of $\widetilde{\mathcal{E}}_{F}^{\text {en }}$ we use the same precision $\eta$ as for our 2-adic approximations used in the course of the calculation of $\widetilde{\mathcal{C}}_{F}$. We obtain a system of generators of $\widetilde{\mathcal{E}}_{F}^{\text {enc }}$ by computing the nullspace of the matrix

$$
B=\left(\begin{array}{c|ccc}
\widetilde{v}_{p_{i}}\left(\varepsilon_{j}\right) & \left\lvert\, \begin{array}{ccc}
2^{\eta} & \ldots & 0 \\
& \cdot & \ldots \\
\cdot \\
& 0 & \ldots
\end{array} 2^{\eta}\right.
\end{array}\right)
$$

with $r+c-1+s+e$ columns and $e$ rows, where $e$ is the cardinality of $P E$ and the precision $\eta$ is determined as explained in [3].

We assume that the nullspace of $B$ is generated by the columns of the matrix

$$
B^{\prime}=\left(\begin{array}{cc}
C & \\
- & - \\
\\
D
\end{array}\right)
$$

where $C$ has $r+c-1+s$ and $D$ exactly $e$ rows. It suffices to consider $C$. Each column $\left(n_{1}, \ldots, n_{r+c-1+s}\right)^{t r}$ of $C$ corresponds to a unit

$$
\prod_{i=1}^{r+c-1+s} \varepsilon_{i}^{n_{i}} \in \widetilde{\mathcal{E}}_{F}^{e x c} \mathcal{R}_{F}^{2^{\eta}}
$$

so that we can choose

$$
\widetilde{\varepsilon}:=\prod_{i=1}^{r+c-1+s} \varepsilon_{i}^{n_{i}}
$$

as an approximation for an exceptional unit. This procedure yields $k \geq$ $r+c+e$ exceptional units, say $\widetilde{\varepsilon}_{1}, \ldots, \widetilde{\varepsilon}_{k}$. By the so-called generalized conjecture of Gross we would have exactly $r+c+e$ such units. So we assume in the following that the procedure does give $k=r+c+e$ (otherwise we would refute the conjecture). Hence, from now on we may assume that we have determined exactly $r+c+e$ generators $\widetilde{\varepsilon}_{1}, \ldots, \widetilde{\varepsilon}_{r+c+e}$ of $\widetilde{\mathcal{E}}_{F}^{\text {exc }}$, and we write:

$$
\widetilde{\mathcal{E}}_{F}^{e x c}=\langle-1\rangle \times\left\langle\widetilde{\varepsilon}_{1}, \ldots, \widetilde{\varepsilon}_{r+c-1+e}\right\rangle .
$$

Definition 8. The kernel of the canonical map $\mathcal{R}_{F} \rightarrow \mathcal{D} \ell_{F}^{\text {pos }}$ is the subgroup of positive logarithmic units:

$$
\widetilde{\mathcal{E}}_{F}^{\text {pos }}=\left\{\widetilde{\varepsilon} \in \widetilde{\mathcal{E}}_{F}^{e x x} \mid \forall \mathfrak{p} \in P L S \quad \operatorname{sg}_{\mathfrak{p}}(\widetilde{\varepsilon})=+1\right\}
$$

The subgroup $\widetilde{\mathcal{E}}_{F}^{\text {pos }}$ has finite index in the group $\widetilde{\mathcal{E}}_{F}^{\text {erc }}$ of exceptional units.
3.2. The algorithm for computing $\mathcal{C} \ell_{\boldsymbol{F}}^{\text {pos. }}$. We assume $P E \neq \emptyset$ and that the logarithmic 2-class group $\widetilde{\mathcal{C} \ell_{F}}$ is isomorphic to the direct sum

$$
\widetilde{\mathcal{C} \ell_{F}} \cong \oplus_{i=1}^{\nu} \mathbb{Z} / 2^{n_{i}} \mathbb{Z}
$$

subject to $1 \leq n_{1} \leq \ldots \leq n_{\nu}$. Let $\mathfrak{a}_{i}(1 \leq i \leq \nu)$ be fixed representatives of the $\nu$ generating divisor classes. Then any divisor $\mathfrak{a}$ of $\mathcal{D} \ell_{F}$ can be written as

$$
\mathfrak{a}=\sum_{i=1}^{\nu} a_{i} \mathfrak{a}_{i}+\lambda \mathfrak{b}+\widetilde{\operatorname{div}}(\alpha)
$$

with suitable integers $a_{i} \in \mathbb{Z}_{2}$, a primitive divisor $\mathfrak{b}, \lambda=\frac{\operatorname{deg}(\mathfrak{a})}{\operatorname{deg}(\mathfrak{b})}$ and an appropriate element $\alpha$ of $\mathcal{R}_{F}$. With each divisor $\mathfrak{a}_{i}$ we associate a vector

$$
\mathbf{e}_{i}:=\left(\operatorname{sg}\left(\mathfrak{a}_{i}, \mathbf{1}\right), 1, \ldots, 1\right) \in\{ \pm 1\}^{m}
$$

where $m$ again denotes the number of divisors in $P L S$. Clearly, that representation then satisfies $\operatorname{sg}\left(\mathfrak{a}_{i}, \mathbf{e}_{i}\right)=1$, hence the element $\left(\mathfrak{a}_{i}, \mathbf{e}_{i}\right)$ belongs to $\mathcal{D} \ell_{F}^{\text {pos }}$. Setting $\mathbf{e}_{\mathfrak{b}}=(\operatorname{sg}(\mathfrak{b}, \mathbf{1}), 1, \ldots, 1)$ as above and writing

$$
\mathbf{e}^{\prime}:=\operatorname{sg}(\alpha) \times \prod_{i=1}^{\nu} \mathbf{e}_{i}^{a_{i}} \times \mathbf{e} \times \mathbf{e}_{\mathfrak{b}}^{\lambda}
$$

for abbreviation, any element $(\mathfrak{a}, \mathbf{e})$ of $\mathcal{D} \ell_{F}^{\text {pos }}$ can then be written in the form

$$
\begin{aligned}
(\mathfrak{a}, \mathbf{e}) & =\left(\sum_{i=1}^{\nu} a_{i} \mathfrak{a}_{i}+\lambda \mathfrak{b}+\widetilde{\operatorname{div}}(\alpha), \mathbf{e}^{\prime} \times \prod_{i=1}^{\nu} \mathbf{e}_{i}^{a_{i}} \times \operatorname{sg}(\alpha) \times \mathbf{e}_{\mathfrak{b}}^{\lambda}\right) \\
& \left.=\sum_{i=1}^{\nu} a_{i}\left(\mathfrak{a}_{i}, \mathbf{e}_{i}\right)+\lambda\left(\mathfrak{b}, \mathbf{e}_{\mathfrak{b}}\right)+\left(\mathbf{0}, \mathbf{e}^{\prime}\right)+\widetilde{(\operatorname{div}}(\alpha), \operatorname{sg}(\alpha)\right)
\end{aligned}
$$

The multiplications are carried out coordinatewise. The vector $\mathbf{e}^{\prime}$ is therefore contained in the $\mathbb{Z}_{2}$-module generated by $\mathbf{g}_{i} \in \mathbb{Z}^{m} \quad(1 \leq i \leq m)$ with $\mathbf{g}_{1}=(1, \ldots, 1)$, whereas $\mathbf{g}_{i}$ has first and $i$-th coordinate -1 , all other coordinates 1 for $i>1$.

As a consequence, the set

$$
\left\{\left(\mathfrak{a}_{j}, \mathbf{e}_{j}\right) \mid 1 \leq j \leq \nu\right\} \cup\left\{\left(0, \mathbf{g}_{i}\right) \mid 2 \leq i \leq m\right\} \cup\{(\mathfrak{b}, \mathbf{e}\}
$$

contains a system of generators of $\mathcal{C} \ell_{F}^{\text {pos }}$ ( note that $\left(0, \mathbf{g}_{1}\right)$ is trivial in $\left.\mathcal{C} \ell_{F}^{\text {pos }}\right)$.
We still need to expose the relations among those. But the latter are easy to characterize. We must have

$$
\begin{aligned}
& \sum_{j=1}^{\nu} a_{j}\left(\mathfrak{a}_{j}, \mathbf{e}_{j}\right)+\sum_{i=2}^{m} b_{i}\left(\mathbf{0}, \mathbf{g}_{i}\right)+\lambda\left(\mathfrak{b}, \mathbf{e}_{\mathfrak{b}}\right) \equiv 0 \bmod \widetilde{\mathcal{P} \ell}{ }_{F}^{p o s}, \\
& \sum_{j=1}^{\nu} a_{j}\left(\mathfrak{a}_{j}, \mathbf{e}_{j}\right)+\sum_{i=2}^{m} b_{i}\left(\mathbf{0}, \mathbf{g}_{i}\right)+\lambda\left(\mathfrak{b}, \mathbf{e}_{\mathfrak{b}}\right)=(\widetilde{\operatorname{div}}(\alpha), \operatorname{sg}(\alpha))+\sum_{\mathfrak{p} \in P E}\left(d_{\mathfrak{p}} \mathfrak{p}, \mathbf{1}\right)
\end{aligned}
$$

with indeterminates $a_{j}, b_{i}, d_{\mathfrak{p}}$ from $\mathbb{Z}_{2}$. Considering the two components separately, we obtain the conditions

$$
\begin{equation*}
\sum_{j=1}^{\nu} a_{j} \mathfrak{a}_{j}+\lambda \mathfrak{b} \equiv \sum_{\mathfrak{p} \in P E} d_{\mathfrak{p}} \mathfrak{p} \bmod \widetilde{\mathcal{P} \ell}{ }_{F} \tag{7}
\end{equation*}
$$

and

$$
\begin{equation*}
\prod_{j=1}^{\nu} \mathbf{e}_{j}^{a_{j}} \times \prod_{i=2}^{m} \mathbf{g}_{i}^{b_{i}} \times \mathbf{e}_{\mathfrak{b}}^{\lambda}=\operatorname{sg}(\alpha) \tag{8}
\end{equation*}
$$

Let us recall that we have already ordered $P L S$ so that exactly the first $e$ elements $\mathfrak{p}_{1}, \ldots, \mathfrak{p}_{e}$ belong to $P E$. Then the first one of the conditions above is tantamount to

$$
\sum_{j=1}^{\nu} a_{j} \mathfrak{a}_{j} \equiv \sum_{i=1}^{e} d_{\mathfrak{p}_{i}}\left(\mathfrak{p}_{i}-\frac{\operatorname{deg} \mathfrak{p}_{i}}{\operatorname{deg} \mathfrak{b}} \mathfrak{b}\right) \bmod \widetilde{\mathcal{P} \ell}
$$

The divisors

$$
\mathfrak{p}_{i}-\frac{\operatorname{deg} \mathfrak{p}_{i}}{\operatorname{deg} \mathfrak{b}}
$$

on the right-hand side can again be expressed by the $\mathfrak{a}_{j}$. For $1 \leq i \leq e$ we let

$$
\widetilde{\operatorname{div}}\left(\alpha_{i}\right)+\mathfrak{p}_{i}-\frac{\operatorname{deg} \mathfrak{p}_{i}}{\operatorname{deg} \mathfrak{b}} \mathfrak{b}=\sum_{j=1}^{\nu} c_{i j} \mathfrak{a}_{j}
$$

The calculation of the $\alpha_{i}, c_{i j}$ is described in [15].
Consequently, the coefficient vectors $\left(a_{1}, \ldots, a_{\nu}, \lambda\right)$ can be chosen as $\mathbb{Z}_{2^{-}}$ linear combinations of the rows of the following matrix $A \in \mathbb{Z}_{2}^{(\nu+e) \times(\nu+1)}$ :

$$
A=\left(\begin{array}{ccccc:c}
2^{n_{1}} & 0 & \cdots & 0 & 0 & 0 \\
0 & 2^{n_{2}} & \cdots & 0 & 0 & 0 \\
\cdot & \cdot & \cdots & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdots & \cdot & \cdot & \cdot \\
0 & 0 & \cdots & 2^{n_{\nu-1}} & 0 & 0 \\
0 & 0 & \cdots & 0 & 2^{n_{\nu}} & 0 \\
-- & -- & --- & -- & -- & --- \\
& & & & & \frac{\operatorname{deg}\left(p_{1}\right)}{\operatorname{deg}(\mathfrak{b})} \\
& & c_{i j} & & & \vdots \\
& & & & & \frac{\operatorname{deg}\left(\mathfrak{p}_{e}\right)}{\operatorname{deg}(\mathfrak{b})}
\end{array}\right) .
$$

Each row $\left(a_{1}, \ldots, a_{\nu}, \lambda\right)$ of $A$ corresponds to a linear combination satisfying

$$
\begin{equation*}
\sum_{j=1}^{\nu} a_{j} \mathfrak{a}_{j}+\lambda \mathfrak{b} \equiv \widetilde{\operatorname{div}}(\alpha) \bmod \mathcal{D} \ell_{F}(P E) \tag{9}
\end{equation*}
$$

Condition (8) gives

$$
\begin{equation*}
\prod_{i=2}^{m} \mathbf{g}_{i}^{b_{i}}=\operatorname{sg}(\alpha) \times \prod_{j=1}^{\nu} \mathbf{e}_{j}^{a_{j}} \times \mathbf{e}_{\mathfrak{b}}^{\lambda} \tag{10}
\end{equation*}
$$

Obviously, the family $\left(\mathbf{g}_{i}\right)_{2 \leq i \leq m}$ is free over $\mathbb{F}_{2}$ implying that the exponents $b_{i}$ are uniquely defined. Consequently, if the $k$-th coordinate of the product $\operatorname{sg}(\alpha) \times \prod_{j=1}^{\nu} \mathbf{e}_{j}^{a_{j}} \times \mathbf{e}_{b}^{\lambda}$ is -1 we must have $b_{k}=1$, otherwise $b_{k}=0$ for $2 \leq k \leq m$. (We note that the product over all coordinates is always 1.) Therefore, we denote by $b_{2, j}, \ldots, b_{m, j}$ the exponents of the relation belonging to the j -th column of $A$ for $j=1, \ldots, \nu+e$.

Unfortunately, the elements $\alpha$ are only given up to exceptional units. Hence, we must additionally consider the signs of the exceptional units of $F$. For

$$
\begin{equation*}
\widetilde{\mathcal{E}}_{F}^{e x}=\langle-1\rangle \times\left\langle\widetilde{\varepsilon}_{1}, \ldots, \widetilde{\varepsilon}_{r+c-1+e}\right\rangle \tag{11}
\end{equation*}
$$

we put:

$$
\begin{equation*}
\operatorname{sg}\left(\widetilde{\varepsilon}_{j}\right)=\prod_{i=1}^{m} \mathbf{g}_{i}^{b_{i, j+v+e}} \tag{12}
\end{equation*}
$$

Using the notations of (11) and (12) the rows of the following matrix $A^{\prime} \in$ $\mathbb{Z}_{2}^{(\nu+2 e+r+c-1) \times(\nu+m)}$ generate all relations for the $\left(\mathfrak{a}_{j}, \mathbf{e}_{j}\right),\left(\mathfrak{b}, \mathbf{e}_{\mathfrak{b}}\right),\left(\mathbf{0}, \mathbf{g}_{i}\right)$.
3.3. The algorithm for computing $\widetilde{\mathcal{C} \ell}{ }_{\boldsymbol{F}}^{\text {pos. }}$. We assume that $P E=$ $\left\{\mathfrak{p}_{1}, \ldots, \mathfrak{p}_{e}\right\} \neq \emptyset$ is ordered by increasing 2 -valuations $v_{2}\left(\operatorname{deg} \mathfrak{p}_{i}\right)$; that the group $\mathcal{C} \ell_{F}^{\text {pos }}$ of positive divisor classes is isomorphic to the direct sum

$$
\mathcal{C} \ell_{F}^{\text {pos }} \cong \oplus_{i=1}^{w} \mathbb{Z} / 2^{m_{i}} \mathbb{Z}
$$

and that we know a full set of representatives $\left(\mathfrak{b}_{i}, \mathbf{f}_{i}\right) \quad(1 \leq i \leq w)$ for all classes.

Then each $(\mathfrak{b}, \mathbf{f}) \in \widetilde{\mathcal{D} \ell_{F}^{\text {pos }}}$ satisfies $\operatorname{deg}(\mathfrak{b}) \in \operatorname{deg}\left(\mathcal{D} \ell_{F}(P E)\right)$ and

$$
\mathfrak{b} \equiv \sum_{i=1}^{w} b_{i} \mathfrak{b}_{i} \bmod \left(\mathcal{D} \ell_{F}(P E)+\widetilde{\mathcal{P} \ell}\right)
$$

Obviously, we obtain

$$
0 \equiv \operatorname{deg}(\mathfrak{b}) \equiv \sum_{i=1}^{w} b_{i} \operatorname{deg}\left(\mathfrak{b}_{i}\right) \bmod \operatorname{deg}\left(\mathcal{D} \ell_{F}(P E)\right)
$$

We reorder the $\mathfrak{b}_{i}$ if necessary so that

$$
v_{2}\left(\operatorname{deg}\left(\mathfrak{b}_{1}\right)\right) \leq v_{2}\left(\operatorname{deg}\left(\mathfrak{b}_{i}\right)\right) \quad(2 \leq i \leq w)
$$

is fulfilled. We put

$$
\begin{aligned}
t & : \\
& =\max \left(\min \left(\left\{v_{2}(\operatorname{deg}(\mathfrak{p})) \mid \mathfrak{p} \in \mathcal{D} \ell_{F}(P E)\right\}\right)-v_{2}\left(\operatorname{deg}\left(\mathfrak{b}_{1}\right)\right), 0\right) \\
& =\max \left(v_{2}\left(\operatorname{deg}\left(\mathfrak{p}_{1}\right)\right)-v_{2}\left(\operatorname{deg}\left(\mathfrak{b}_{1}\right), 0\right)\right.
\end{aligned}
$$

and

$$
\delta:=b_{1}+\sum_{i=2}^{w} \frac{\operatorname{deg}\left(\mathfrak{b}_{i}\right)}{\operatorname{deg}\left(\mathfrak{b}_{1}\right)} b_{i} .
$$

Then we get:

$$
\mathfrak{b} \equiv \sum_{i=2}^{w} b_{i}\left(\mathfrak{b}_{i}-\frac{\operatorname{deg}\left(\mathfrak{b}_{i}\right)}{\operatorname{deg}\left(\mathfrak{b}_{1}\right)} \mathfrak{b}_{1}\right)+\delta \mathfrak{b}_{1} \bmod \left(\mathcal{D} \ell_{F}(P E)+\widetilde{\mathcal{P} \ell}{ }_{F}\right)
$$

and so

$$
\operatorname{deg} \mathfrak{b} \equiv 0 \equiv \sum b_{i} \times 0+\delta \operatorname{deg} \mathfrak{b}_{1} \bmod \operatorname{deg} \mathcal{D} \ell_{F}(P E)
$$

From this it is immediate that a full set of representatives of the elements of $\widetilde{\mathcal{C} \ell}{ }_{F}^{\text {pos }}$ is given by

$$
\left(\mathfrak{b}_{i}-\frac{\operatorname{deg}\left(\mathfrak{b}_{i}\right)}{\operatorname{deg}\left(\mathfrak{b}_{1}\right)} \mathfrak{b}_{1}, \mathbf{f}_{i} \times \mathbf{f}_{1}^{-\operatorname{deg}\left(\mathfrak{b}_{i}\right) / \operatorname{deg}\left(\mathfrak{b}_{1}\right)}\right) \text { for } 2 \leq i \leq w
$$

and

$$
\left(\mathfrak{b}_{1}^{\prime}:=2^{t} \mathfrak{b}_{1}-2^{t} \frac{\operatorname{deg} \mathfrak{b}_{1}}{\operatorname{deg} \mathfrak{p}_{1}} \mathfrak{p}_{1}, \mathbf{f}_{1}^{2^{t}}\right)
$$

Let us denote the class of $(\mathbf{c}, \mathbf{f})$ in $\widetilde{\mathcal{C} \ell_{F}^{\text {pos }}}$ by $[\mathbf{c}, \mathbf{f}]$.
Now we establish a matrix of relations for the generating classes. For this we consider relations:

$$
\sum_{i=2}^{w} a_{i}\left[\mathfrak{b}_{i}-\frac{\operatorname{deg}\left(\mathfrak{b}_{i}\right)}{\operatorname{deg}\left(\mathfrak{b}_{1}\right)} \mathfrak{b}_{1}, \mathbf{f}_{i} \times \mathbf{f}_{1}^{-\frac{\operatorname{deg}\left(\mathfrak{b}_{i}\right)}{\operatorname{deg}\left(\mathfrak{b}_{1}\right)}}\right]+a_{1}\left[2^{t} \mathfrak{b}_{1}^{\prime}, \mathbf{f}_{1}^{2^{t}}\right]=0
$$

hence

$$
\sum_{i=2}^{w} a_{i}\left[\mathfrak{b}_{i}, \mathbf{f}_{i}\right]+\left(2^{t} a_{1}-\sum_{i=2}^{w} \frac{\operatorname{deg}\left(\mathfrak{b}_{i}\right)}{\operatorname{deg}\left(\mathfrak{b}_{1}\right)} a_{i}\right)\left[\mathfrak{b}_{1}, \mathbf{f}_{1}\right]=0
$$

A system of generators for all relations can then be computed analogously to the previous section. We calculate a basis of the nullspace of the matrix $A^{\prime \prime}=\left(a_{i j}^{\prime \prime}\right) \in \mathbb{Z}^{w \times 2 w}$ with first row

$$
\left(2^{t},-\frac{\operatorname{deg}\left(\mathfrak{b}_{2}\right)}{\operatorname{deg}\left(\mathfrak{b}_{1}\right)}, \ldots,-\frac{\operatorname{deg}\left(\mathfrak{b}_{w}\right)}{\operatorname{deg}\left(\mathfrak{b}_{1}\right)}, 2^{m_{1}}, 0, \ldots, 0\right)
$$

and in rows $i=2, \ldots, w$ all entries are zero except for $a_{i i}^{\prime \prime}=1$ and $a_{i, w+i}^{\prime \prime}=$ $2^{m_{i}}$. We note that we are only interested in the first $w$ coordinates of the obtained vectors of that nullspace.

## 4. Examples

The methods described here are implemented in the computer algebra system Magma [2]. Many of the fields used in the examples were results of queries to the QaoS number field database [5, section 6]. More extensive tables of examples can be found at:

```
http://www.math.tu-berlin.de/~ pauli/K
```

In the tables abelian groups are given as a list of the orders of their cyclic factors.
[:] denotes the index $\left(K_{2}\left(O_{F}\right): W K_{2}(F)\right)$ (see [1, equation (6)]);
$d_{F}$ denotes the discriminant for a number field $F$;
$\mathcal{C} \ell_{F}$ denotes the class group, $P$ the set of dyadic places;
$\mathcal{C} \ell_{F}^{\prime}$ denotes the 2-part of $\mathcal{C} \ell /\langle P\rangle$;
$\widetilde{\mathcal{C}} \ell_{F}$ denotes the logarithmic classgroup;
$\mathcal{C} \ell_{F}^{\text {pos }}$ denotes the group of positive divisor classes;
$\widetilde{\mathcal{C}} \ell_{F}^{\text {pos }}$ denotes the group of positive divisor classes of degree 0 ;
$r k_{2}$ denotes the 2-rank of the wild kernel $W K_{2}$.
K. Belabas and H. Gangl have developed an algorithm for the computation of the tame kernel $K_{2} \mathcal{O}_{F}$ [1]. The following table contains the structure of $K_{2} \mathcal{O}_{F}$ as computed by Belabas and Gangl and the 2-rank of the wild kernel $W K_{2}$ calculated with our methods for some imaginary quadratic fields. We also give the structure of the wild kernel if it can be deduced from the structure of $K_{2} \mathcal{O}_{F}$ and of the rank of the wild kernel computed here or in [15].

### 4.1. Imaginary quadratic fields.

| $d_{F}$ | $\mathcal{C} \ell_{F}$ | $K_{2} \mathcal{O}_{F}$ |  | $\|P\|\|P E\|$ | $\mathcal{C} \ell_{F}^{\prime}$ |  | $\mathcal{C} \ell_{F}^{\text {pos }}$ | $\widetilde{\mathcal{C}} \underbrace{\text { pos }}_{F}$ | $r k_{2} W K_{2}$ |  |
