## A generalization of a theorem of Erdös on asymptotic basis of order 2

#### par Martin Helm

ABSTRACT – Let T be a system of disjoint subsets of  $\mathbb{N}^*$ . In this paper we examine the existence of an increasing sequence of natural numbers, A, that is an asymptotic basis of all infinite elements  $T_j$  of T simultaneously, satisfying certain conditions on the rate of growth of the number of representations  $r_n(A); r_n(A) := |\{(a_i, a_j) : a_i < a_j; a_i, a_j \in A; n = a_i + a_j\}|$ , for all sufficiently large  $n \in T_j$  and  $j \in \mathbb{N}^*$ . A theorem of P. Erdös is generalized.

#### 1. Notation

In this paper,  $\mathbb{N}^*$  will always denote the set of integers  $\{1, 2, \ldots, n, \ldots\}$ . An increasing sequence of natural numbers, A, is called an asymptotic basis of order 2 of a given set T of natural numbers if every sufficiently large  $n \in T$  has at least one representation in the form  $n = a_i + a_j$ ;  $a_i < a_j$ ;  $a_i, a_j \in A$ . Let  $r_n(A)$  be the number of such representations of  $n \in T$  by elements of A.

DEFINITION. A system  $T = (T)_{j \in \mathbb{N}^*}$  of disjoints subsets of  $\mathbb{N}^*$  satisfying  $\mathbb{N}^* = \bigcup_{j=1}^{\infty} T_j$  is called a disjoint covering system.

DEFINITION. If for an increasing sequence A of natural numbers there exists a disjoint covering system T such that

- (1)  $\exists j_0 : T_j = \emptyset \ \forall j \geq j_0 \ or \ |T_j| = \infty \ for \ infinitively \ many \ j \in \mathbb{N}^*$  and
- (2) A is an asymptotic basis of order 2 of all infinite elements  $T_j$  of T,

then A is called an asymptotic pseudo-basis of  $\mathbb{N}^*$ .

*Remark.* Let A be an asymptotic pseudo-basis in regard to a disjoint covering system  $\mathcal{T}$ . For any infinite element  $T_i$  of  $\mathcal{T}$  let

$$n_j := \min\{m \in T_j : r_n(A) > 0 \quad \forall n \in T_j, \ n \ge m\}.$$

Obviously any asymptotic basis A of order 2 of  $\mathbb{N}^*$  is an asymptotic pseudobasis (e.g. for  $\mathcal{T} := \mathbb{N}^*, \emptyset, \emptyset, ...$ ). But unfortunately the converse in general is not true since for any asymptotic pseudo-bases A of  $\mathbb{N}^*$  together with a corresponding disjoint covering system  $\mathcal{T}$  the set of all  $n_j$  that are defined in the above sense is not necessarily bounded.

#### 2. Introduction

More than fifty years ago S. Sidon [5] asked if there exists an asymptotic basis of order 2 of  $\mathbb{N}^*$  that is economic in the sense that for every  $\varepsilon > 0$  the assumption  $\lim_{n \to \infty} \frac{r_n(A)}{n^{\varepsilon}} = 0$  holds.

In 1953 P. Erdös [1] solved this problem ingeniously. In fact he proved the much sharper:

THEOREM. There exists an asymptotic basis A of order 2 of  $\mathbb{N}^*$ , satisfying:

(3) 
$$A(n) \sim \alpha \ n^{\frac{1}{2}} (\log n)^{\frac{1}{2}} , \alpha \in \mathbb{R},$$

with 
$$A(n) := \sum_{a \in A, 1 \le a \le n} 1$$

and

(4) 
$$\log n \ll r_n(A) \ll \log n.$$

An attractive and still open problem is to decide whether there exists a basis A of  $\mathbb{N}^*$  for which there exists  $c := \lim_{n \to \infty} \frac{r_n(A)}{\log n}$ .

Moreover in [4] I. Rusza asks for a basis for which  $r_n(A) \ll \frac{\log n}{\log_2 n}$  holds.

#### 3. On asymptotic pseudo-bases

In this paper we prove the following:

THEOREM. For any  $k \in \mathbb{N}^*$  there exists a disjoint covering system  $\mathcal{T}^{(k)} = \{T_1^{(k)}, T_2^{(k)}, ...\}$  satisfying:

 $\forall j \in \mathbb{N}^* : T_i^{(k)}$  is an infinite element of  $\mathcal{T}^{(k)}$ :

(5) 
$$\log_{k-1} n \gg T_j^{(k)}(n) \gg \log_{k-1} n \ (n \to \infty)$$

$$(where \log_0 n := id(n) = n),$$

and an asymptotic pseudo-basis A satisfying:

(6) 
$$A(n) \sim 2\alpha(\log_k n)^{\frac{1}{2}} n^{\frac{1}{2}}$$

and

$$c_1 \log_k n \le r_n(A) \le c_2 \log_k n,$$

(7)  $\forall n \in T_j^{(k)}$  that are sufficiently large, and  $\forall j \in \mathbb{N}^*$  where  $T_j^{(k)}$  is an infinite element of  $\mathcal{T}^{(k)}$ ,

where  $\alpha, c_1$  and  $c_2$  are global real constants not depending on j.

*Remark.* The above theorem generalizes (3,4), which is just the special case k=1 (e.g. with  $\mathcal{T}:=\mathbb{N}^*,\emptyset,\emptyset,\ldots$ ).

The proof of the above theorem is based on a slight modification of Erdös' proof of (3,4). Therefore like the proof of (3,4), it is based on a probabilistic method and not constructive.

### 3.1 Inductive construction of suitable disjoint covering systems

First of all, for any  $k \in \mathbb{N}^*$ , we are going to construct a special disjoint covering system  $\mathcal{T}^{(k)}$  satisfying (1) and (5).

The case k = 1.

For k = 1 let  $\mathcal{T}^{(1)} := \mathbb{N}^*, \emptyset, \emptyset, \cdots$ .

Obviously  $\mathcal{T}^{(1)}$  is a disjoint covering system and (1) and (5) hold.

The case k=2.

For k=2 we define  $\mathcal{T}^{(2)}$  inductively as follows:

$$T_1^{(2)} := \{1\},\,$$

$$T_2^{(2)}:=\{2^j\ :\ j\in\mathbb{N}^*\}.$$

Now, if  $T_1^{(2)}, \dots, T_r^{(2)}$  are already defined, let:

$$s:=\min\{n\in\mathbb{N}^*\ :\ n\notin\bigcup_{i=1}^r T_i^{(2)}\}$$

and we define

$$T_{r+1}^{(2)} := \{ s^j : j \in \mathbb{N}^* \}.$$

Now we consider the following equivalence relation on N\*:

$$a \sim b : \iff \exists s, u, v \in \mathbb{N}^* : a = s^u, b = s^v.$$

 $\mathcal{T}^{(2)}$  just consists of all equivalence classes concerning the above equivalence relation. Thus  $\mathcal{T}^{(2)}$  is a disjoint covering system and obviously (1) holds. For  $\mathcal{T}_i^{(2)} \in \mathcal{T}^{(2)} \setminus \{1\}$  there exists  $s \in \mathbb{N}^*$  such that

$$T_i^{(2)} = \{ s^j : j \in \mathbb{N}^*, s \in \mathbb{N}^* \setminus \{1\} \}.$$

For any sufficiently large  $m \in \mathbb{N}^*$  there exists  $t \in \mathbb{N}^*$  such that

$$s^t \le m < s^{t+1}.$$

Thus  $T_i^{(2)}(m) = t$  implies that:

$$T_i^{(2)}(m) \le \frac{1}{\log s} \log m \le T_i^{(2)}(m) + 1,$$

and consequently

$$\log m \ll T_i^{(2)}(m) \ll \log m.$$

Therefore also (5) holds.

The case k=3.

DEFINITION. For  $s \in \mathbb{N}^*$  and any non-empty subset M of  $\mathbb{N}^*$  we define

$$s^M := \{s^m : m \in M\}.$$

We construct  $\mathcal{T}^{(3)}$  by dividing every element  $\mathcal{T}_i^{(2)}$  of  $\mathcal{T}^{(2)}$  except  $\{1\}$  into disjoint infinite subsets of  $\mathbb{N}^*$ .

For any  $\mathcal{T}_i^{(2)}$  of  $\mathcal{T}^{(2)}$  there exists  $s \in \mathbb{N}^*$ :

$$\mathcal{T}_i^{(2)} = \{ s^j : j \in \mathbb{N}^* \}.$$

Consequently

$$\mathcal{T}_i^{(2)} = \bigcup_{\mathcal{T}_j^{(2)} \in \mathcal{T}^{(2)}} s^{\mathcal{T}_j^{(2)}}$$

and we define  $\mathcal{T}^{(3)}$  as the system of all those sets  $s^{\mathcal{T}_j^{(2)}} = \{s^{p^j}: j \in \mathbb{N}^*\}$  where p is a natural constant. Since  $\mathcal{T}^{(2)}$  is a disjoint covering system,  $\mathcal{T}^{(3)}$  is a disjoint covering system, too; and as (1) holds for  $\mathcal{T}^{(2)}$ ,  $\mathcal{T}^{(3)}$  satisfies (1), too.

For any infinite element  $\mathcal{T}_{i}^{(3)}$  for  $\mathcal{T}^{(3)}$  and any sufficiently large number  $m \in \mathbb{N}^*$  there exist  $s, p, t \in \mathbb{N}^*$  such that

$$\mathcal{T}_i^{(3)} = \{ s^{p^j} : j \in \mathbb{N}^* \},$$

and

$$s^{p^t} \leq m < s^{p^{t+1}}.$$

Then  $\mathcal{T}_i^{(3)}(m) = t$  implies  $\log_2 m \ll \mathcal{T}_i^{(3)}(m) \ll \log_2 m$ . Consequently  $\mathcal{T}^{(3)}$  satisfies also (5).

The general case  $k \geq 4$ .

Let  $\mathcal{T}^{(1)}, \mathcal{T}^{(2)}, \mathcal{T}^{(3)}, \cdots \mathcal{T}^{(k)}$  be already constructed by the above procedure. Thus for every infinite element  $\mathcal{T}_i^{(k)}$  of  $\mathcal{T}^{(k)}$  there exist  $s_1, \cdots, s_{k-1} \in \mathbb{N}^*$  so that

$$\mathcal{T}_i^{(k)} = \{s_1^{\left( \cdot \cdot \cdot ^{(s_{k-1}^j)} \right)} \ : \ j \in \mathbb{N}^*\},$$

and according to the above procedure  $\mathcal{T}^{(k+1)}$  will be constructed out of  $\mathcal{T}^{(k)}$  by dividing every infinite  $\mathcal{T}_i^{(k)}$  of  $\mathcal{T}^{(k)}$  into disjoint subsets

$$s_1^{\left(\binom{T_i^{(2)}}{s_i^{k-1}}\right)}, T_i^{(2)} \in \mathcal{T}^{(2)}.$$

It is easy to see that also  $\mathcal{T}^{(k+1)}$  is a disjoint covering system satisfying (1) and (5).

## 3.2 Proof of the existence of an asymptotic pseudo-basis A satisfying (6) and (7) in regard to $\mathcal{T}^{(k)}$ for any fixed $k \in \mathbb{N}^*$ .

This part of the proof of the above theorem uses the probabilistic method of Erdös and Rényi [2]. Since [3] contains an excellent exposition of it, we only give a short survey of those of Erdös' and Rényi's ideas our next steps are based on without proof.

*Remark.* Since, as we mentioned above, the case k=1 is already solved we restrict ourselves to the case  $k \geq 2$ .

By the method of Erdös and Rényi ([2] and [3]) for any sequence of real numbers  $(\alpha_j)_{j\in\mathbb{N}^{\bullet}}$ ,  $0 \le \alpha_j \le 1$ , there exists a probability space with probability measure  $\mu$  on the space  $\Omega$  of all strictly increasing sequences of natural numbers, satisfying:

- (8) the event  $B^{(n)} := \{ \omega \in \Omega : n \in \Omega \}$  is measurable,  $\mu(B^{(n)}) = \alpha_n$ ,
- (9) and the events  $B^{(1)}$ ,  $B^{(2)}$ ,  $\cdots$  are independent.

We denote by  $\rho_n$  the characteristic function of the event  $B^{(n)}$ . From now on we consider only those sequences of probabilities ( $\alpha_i$ 

From now on we consider only those sequences of probabilities  $(\alpha_j)_{j\in\mathbb{N}^{\bullet}}$ , satisfying :

$$(10) 0 < \alpha_j < 1,$$

(11) 
$$\lim_{j \to \infty} \alpha_j = 0,$$

$$\exists j_0 : \alpha_{j+1} < \alpha_j \ \forall j \geq j_0,$$

(13) 
$$\sum_{j=1}^{\infty} \alpha_j = \infty.$$

Then by a particular variant of the strong law of large numbers, with probability 1,

(14) 
$$\sum_{j=1}^{n} \alpha_j \sim \omega(n) \ (n \to \infty)$$

holds, where

(15) 
$$\omega(n) := \sum_{j \in \omega; 1 \le j \le n} 1.$$

Let

$$\lambda_n := \sum_{1 \le j < \frac{n}{2}} \alpha_j \alpha_{n-j}, \ m_n := \sum_{j=1}^n \alpha_j,$$

and

$$\lambda_n' := \sum_{1 \leq j < \frac{n}{2}} \alpha_j \alpha_{n-j} (1 - \alpha_j \alpha_{n-j})^{-1}.$$

Then we have:

(16) 
$$\lambda_n' \sim \lambda_n \ (n \to \infty),$$

and

(17) 
$$\mu(\{\omega: r_n(\omega) = d\}) \le \frac{\lambda_n'^d}{d!} e^{-\lambda_n}, \ d \in \mathbb{N}.$$

LEMMA 1. A sequence  $(\alpha_j)_{j\in\mathbb{N}^*}$  of positive real numbers is defined by

(18) 
$$\alpha_j := \alpha \frac{(\log_k j)^{c'}}{j^c} \quad \forall j > j_0,$$

where  $j_0, \alpha, k, c$  and c' are suitably chosen real constants, satisfying

$$0 \le c', \qquad 0 < c < 1, \qquad 0 < \alpha, \qquad 1 \le k$$

so that  $\log_k(j) > 0$ ,  $\forall j > j_0$  and (18) and (10 - 13) are compatible. The precise value of  $\alpha_j$  for small j is unimportant in case that their choice ensures that (18) and (10 - 13) are compatible also for  $\alpha_1, \dots, \alpha_{j_0}$ . Then as  $(n \to \infty)$ 

(19) 
$$\lambda_n \sim \frac{1}{2} \alpha^2 \frac{(\Gamma(1-c))^2}{\Gamma(2-2c)} (\log_k n)^{2c'} n^{1-2c}$$

(20) 
$$m_n \sim \frac{\alpha}{1-c} (\log_k n)^{c'} n^{1-c}.$$

Remark. The above lemma is a slight generalization of Lemma 11 in [3], p 144. Its proof corresponds essentially to that of the above-mentioned Lemma 11 and is therefore left to the reader.

Now let k be a fixed natural number. To prove our theorem, corresponding to Erdös' proof of (3,4), we first choose a number  $\alpha$  with  $0 < \alpha < 1$ , so that

$$(21) \qquad \qquad \frac{1}{2}\alpha^2\pi > 1$$

holds, and we define the sequence  $(\alpha_i)_{i\in\mathbb{N}^*}$  by

(22) 
$$\alpha_{j} = \begin{cases} \frac{1}{2} & 1 \leq j \leq j_{0}, \\ \alpha \frac{(\log_{k} n)^{\frac{1}{2}}}{j^{\frac{1}{2}}} & j > j_{0}, \end{cases}$$

where  $j_0$  is a suitably chosen natural number so that  $\log_k j > 0 \quad \forall j > j_0$  and  $(\alpha_j)_{j \in \mathbb{N}^*}$  satisfies (10 - 13).

Therefore by (14) and by Lemma 1 we have with probability 1

(23) 
$$\omega(n) \sim 2\alpha \sqrt{\log_k n} \sqrt{n},$$

(24) 
$$\lambda_n \sim \frac{\pi}{2} \alpha^2 \log_k n,$$

which because of (21) ensures the existence of a number  $\delta > 0$  such that

(25) 
$$e^{-\lambda_n} \ll (\log_{k-1} n)^{-(1+\delta)}$$
.

In view of (17) for any  $n \in \mathbb{N}^*$ ,  $d \in \mathbb{N}$ :

$$\mu(\{\omega : r_n(\omega) > e\lambda'_n\}) \leq \sum_{d \geq e\lambda'_n} \mu(\{\omega : r_n(\omega) = d\}) \leq \sum_{d \geq e\lambda'_n} \frac{\lambda''_n}{d!} e^{-\lambda_n}$$

$$\leq \left(\frac{e\lambda'_n}{e\lambda'_n}\right)^{e\lambda'_n}e^{-\lambda_n} = e^{-\lambda_n} \ll \frac{1}{(\log_{k-1}n)^{1+\delta}}.$$

Let  $T_i^{(k)}$  be an infinite non-empty element of  $\mathcal{T}^{(k)}$ .

There exists  $s_1, \dots, s_{k-1} \in \mathbb{N}^*$  so that

$$T_i^{(k)} = \{s_1^{\left(\frac{\cdot \cdot \cdot (s_{k-1}^j)}{s_2}\right)}, j \in \mathbb{N}^*\}.$$

Consequently:

$$\sum_{n \in T_i^{(k)}} \mu(\{\omega : r_n(\omega) > e \ \lambda_n'\}) \le \sum_{n \in T_i^{(k)}} e^{-\lambda_n}$$

$$\le \sum_{j=1}^{\infty} \left( \log_{k-1} s_1^{\left(s_2^{(s_{k-1}^{(s_{k-1}^j)})}\right) \right)^{-(1+\delta)}$$

$$\ll \sum_{j=1}^{\infty} \left(\frac{1}{j}\right)^{1+\delta} < \infty.$$

Therefore the application of the Borel-Cantelli-Lemma proves the existence of a positive real number  $c_2$ , such that for any infinite  $T_i^{(k)} \in \mathcal{T}^{(k)}$ 

(26) 
$$\mu(\{\omega : r_n(\omega) \le c_2 \log_k n, n \in T_i^{(k)}, (n \text{ sufficiently large})\}) = 1.$$

On the other hand for any suitably chosen constant b < 1 again in view of (17) we have

$$\mu(\{\omega : r_n(\omega) < b\lambda'_n\}) \leq \sum_{1 \leq d \leq b\lambda'_n} \mu(\{\omega : r_n(\omega) = d\})$$

$$\leq \sum_{1 \leq d \leq b\lambda'_n} \frac{\lambda'_n^d}{d!} e^{-\lambda_n}$$

$$\leq \left(\frac{e\lambda'_n}{b\lambda'_n}\right)^{b\lambda'_n} e^{-\lambda_n}$$

$$= \left[\left(\frac{e}{b}\right)^b\right]^{\lambda'_n} e^{-\lambda_n}.$$

Therefore because of (16) there exists  $c_1$ ,  $0 < c_1 < 1$  such that

(27) 
$$[(\frac{e}{c_1})^{c_1}]^{\lambda'_n} e^{-\lambda_n} \ll (\log_{k-1} n)^{-(1+\frac{\delta}{2})}.$$

Thus for any fixed infinite  $T_i^{(k)} \in \mathcal{T}^{(k)}$ , with

$$T_i^{(k)} = \{s_1^{\left(s_2^{(s_{k-1}^j)}\right)}, j \in \mathbb{N}^*\},$$

we have

$$\sum_{n \in T_i^{(k)}} \mu(\{\omega : r_n(\omega) < c_1 \lambda_n'\}) \ll \sum_{j=1}^{\infty} \left( \log_{k-1} s_1^{\binom{s_2^j - s_1}{s_2^j}} \right)$$

$$\ll \sum_{j=1}^{\infty} (\frac{1}{j})^{1 + \frac{\delta}{2}} < \infty.$$

Again we apply the Borel-Cantelli-Lemma to prove the existence of  $c_1 > 0$  such that for any infinite  $T_i^{(k)} \in \mathcal{T}^{(k)}$ 

(28) 
$$\mu(\{\omega : r_n(\omega) \ge c_1 \log_k n, n \in T_i^{(k)}, (n \text{ sufficiently large})\}) = 1.$$

We have shown that  $\omega$  has each of the desired properties with probability 1 and thus the whole proof is complete.
