# Continued Fractions, Multidimensional Diophantine Approximations and Applications 

par Nikolai G. MOSHCHEVITIN

Résumé. Cet article rassemble des résultats généraux d'approximation diophantienne, sur les meilleures approximations et leurs applications à la théorie de répartition uniforme.

Abstract. This paper is a brief review of some general Diophantine results, best approximations and their applications to the theory of uniform distribution.

## 1. Diophantine approximations.

### 1.1. One-dimensional approximations.

1.1.1. Lagrange spectrum. Let $\alpha$ be an irrational number. Dirichlet's theorem states that there are infinitely many positive integers $q$ such that

$$
\|q \alpha\|<\frac{1}{q}
$$

holds, where $\|\cdot\|$ denotes the distance to the nearest integer. Hurwitz obtained a more precise result: for any irrational number $\alpha$, the inequality

$$
\|q \alpha\|<\frac{1}{\sqrt{5} q}
$$

has infinitely many solutions in $q$. Moreover, there is a countable set of numbers $\alpha$ for which this inequality is an exact one, that is, for any positive $\varepsilon$ there are only finitely positive integers $q$ such that the inequality

$$
\|q \alpha\|<\left(\frac{1}{\sqrt{5}}-\varepsilon\right) \frac{1}{q}
$$

holds.
We define the Lagrange spectrum to be the set of the real numbers $\lambda$ for which there exists $\alpha=\alpha(\lambda)$ such that the inequality

$$
\|q \alpha\|<\lambda \frac{1}{q}
$$

has infinitely many solutions, and for any positive $\varepsilon$ the inequality

$$
\|q \alpha\|<(\lambda-\varepsilon) \frac{1}{q}
$$

has only a finite number of solutions. It is well-known that Lagrange spectrum has a discrete part

$$
\frac{1}{\sqrt{5}}, \frac{1}{\sqrt{8}}, \ldots
$$

and the minimal $\lambda$ for which there are uncountably many $\alpha=\alpha(\lambda)$ is $\lambda=1 / 3$. Also it is well-known that Lagrange spectrum contains an interval [ $0, \lambda^{*}$ ].

Moreover, for any decreasing function $\psi$ satisfying $\psi(y)=o\left(y^{-1}\right)$, as $y$ tends to infinity, there is an uncountable set of real numbers $\alpha$ such that the inequality

$$
\|q \alpha\|<\psi(q)
$$

has infinitely many solutions, but for any $\varepsilon>0$, the stronger inequality

$$
\|q \alpha\|<(1-\varepsilon) \psi(q)
$$

has only a finite number of solutions.
One can find the above results in [5]. All of them can be obtained from the continued fraction expansion [14].
1.1.2. Best approximations and continued fractions. Any real number $\alpha$ may be written as

$$
\alpha=b_{0}+\frac{1}{b_{1}+\frac{1}{b_{2}+\frac{1}{b_{3}+\ldots}}}
$$

where $b_{0} \in \mathbb{Z}$ and, for $j>0, b_{j}$ are a nonnegative integers. For convenience, we use the notation

$$
\alpha=\left[b_{0} ; b_{1}, b_{2}, b_{3}, \ldots\right]
$$

This representation is infinite and unique when $\alpha$ is irrational. If $\alpha$ is rational, we have $\alpha=\left[b_{0} ; b_{1}, b_{2}, b_{3}, \ldots, b_{t}\right]$, and this representation is unique if we impose the condition $b_{t} \neq 0,1$.

Convergents to $\alpha$ of the order $\nu$ are defined as

$$
\frac{p_{\nu}}{q_{\nu}}=\left[b_{0} ; b_{1}, b_{2}, b_{3}, \ldots, b_{\nu}\right]
$$

A simple theorem states that these fraction and only these form the best approximations, that is the relation

$$
\left\|q_{\nu} \alpha\right\|=\min _{q<q_{\nu}}\|q \alpha\|
$$

holds for the denominators $q_{\nu}$ and only for them (see [14]). We now give two other easy facts.

Theorem 1. We have

$$
\left\|q_{\nu} \alpha\right\| \asymp\left(q_{\nu+1}\right)^{-1}, \quad \text { (in order of approximation) }
$$

Proposition 2. We have

$$
\Delta_{\nu}=\left|\begin{array}{cc}
p_{\nu} & q_{\nu} \\
p_{\nu+1} & q_{\nu+1}
\end{array}\right|= \pm 1
$$

1.1.3. Klein polygons. We now consider the integer lattice $\mathbb{Z}^{2} \subset \mathbb{R}^{2}$. Let $(q, a) \in \mathbb{Z}^{2}$ be a primitive point $(\operatorname{gcd}(q, a)=1)$ and $q, a>0$. We define the two angles $\varphi_{+}$and $\varphi_{-}$by

$$
\begin{aligned}
& \varphi_{+}=\left\{Z=(x, y) \in \mathbb{R}^{2}: x \geq 0, y \geq \frac{a}{q} x\right\} \\
& \varphi_{-}=\left\{Z=(x, y) \in \mathbb{R}^{2}: \quad y \geq 0, y \leq \frac{a}{q} x\right\}
\end{aligned}
$$

Klein polygons $\mathcal{K}_{+}(a, q)$ and $\mathcal{K}_{-}(a, q)$ are defined to be respectively the following borders

$$
\partial\left(\operatorname{conv}\left(\varphi_{+} \cap\left(\mathbb{Z}^{2} \backslash\{0\}\right)\right)\right)
$$

and

$$
\partial\left(\operatorname{conv}\left(\varphi_{-} \cap\left(\mathbb{Z}^{2} \backslash\{0\}\right)\right)\right)
$$

which consist of finite (nontrivial) intervals.
We now define $\Delta(a, q)$ to be the domain:

$$
\begin{aligned}
\Delta(a, q)=\{Z & =(x, y) \in \mathbb{R}^{2}: x>0, y>0 \\
& \left.Z \notin \operatorname{conv}\left(\varphi_{+} \cap\left(\mathbb{Z}^{2} \backslash\{0\}\right)\right), \quad Z \notin \operatorname{conv}\left(\varphi_{-} \cap\left(\mathbb{Z}^{2} \backslash\{0\}\right)\right)\right\}
\end{aligned}
$$

We have
Theorem 3 ([7, 9]). 1. The vertices of $\mathcal{K}_{-}(a, q)$, (different from $(q, a)$ ) are integer points of the form $\left(q_{2 \mu}, p_{2 \mu}\right)$, where $\left(p_{2 \mu} / q_{2 \mu}\right)$ is the $2 \mu$-th convergent to $a / q$.
2. The vertices of $\mathcal{K}_{+}(a, q)$ (different from $(q, a)$ ) are integer points of the form $\left(q_{2 \nu+1}, p_{2 \nu+1}\right)$, where $p_{2 \nu+1} / q_{2 \nu+1}$ is the $(2 \nu+1)$-th convergent to a/q. 3. If $(u, v) \in\left(\mathcal{K}_{+}(a, q) \cup \mathcal{K}_{-}(a, q)\right) \cap \mathbb{Z}^{2}$ is an integer point then $v / u$ is a convergent to $a / q$ or one of the intermediate fractions $\left(w p_{\nu}+p_{\nu-1}\right) /\left(w q_{\nu}+\right.$ $\left.q_{\nu-1}\right), 1 \leq w \leq b_{\nu+1}$.
4. $\Delta(a, q) \cap \mathbb{Z}^{2}=\emptyset$.

One can easily verify the same results for infinite continued fractions (i.e. for irrational numbers).

Recently, several papers [1, 21, 45, 46, 27] devoted to multidimensional generalization of Klein polygons have appeared. Unfortunately one must notice that there is something incorrect in papers [45, 46].
1.1.4. Representation of rationals. The rationals $a / q$ with bounded partial quotients $b_{j}$ are of great interest (see [22, 23, 24, 11]).

Let $N(k, q)$ be the number of integers $A, 1 \leq A<q, \operatorname{gcd}(A, q)=1$ such that any component $b_{i}$ of the continued fraction expansion

$$
\frac{A}{q}=\left[0 ; b_{1}, \ldots, b_{n(A)}\right]
$$

is bounded by $k$ : $b_{i} \leq k, i=1, \ldots, n(A)$. It is known ([22, 4, 52]) that if $k>\gamma \log q$ with $\gamma$ sufficiently large, then $N(k, q) \geq 1$. Moreover we can show that for almost all positive integers $q$ and $A$ with $1 \leq A<q$, all partial quotients are bounded by $O(\log q)$.
By the way we may recall a famous and still open conjecture which asserts that for any $q \geq 1$, we have $N(6, q) \geq 1$. However it is known that the conjecture holds when $q=2^{\alpha}$ or $q=3^{\alpha}$ ([39]).

Sergei Konyagin (see [17]), by means of Farey fractions, proved the following upper bound for $N(k, q)$ :

Theorem 4. For any $\gamma<1$ and for any $k \geq k(\gamma)$ we have

$$
N(k, q) \ll \varphi(q) q^{-\frac{\gamma}{k \log ^{k} k}},
$$

where $\varphi$ denotes the Euler function.
We define the sequence $A_{1}<A_{2}<\cdots<A_{d}$ to be an almost arithmetic progression if

$$
\exists w>1: \quad w \leq A_{j+1}-A_{j} \leq 3 w, j=1, \ldots, d-1 .
$$

In [32], the author shows that numbers with bounded partial quotients cannot appear very regularly: they cannot form long almost arithmetic progressions. The following theorem improves the result from [32].

Theorem 5. For $d \geq 3$, let $A_{0}, \ldots, A_{d}$ be positive integers. Suppose
(i) $0<A_{0}<\ldots<A_{d}$ form an almost arithmetic progression;
(ii) $\operatorname{gcd}\left(A_{i}, q\right)=1, i=0, \ldots, d$.

Let $A_{\nu} / q=\left[b_{\nu, 1}, \ldots, b_{\nu, s(\nu)}\right]$. Then there exist $\nu_{0}$ and $\mu_{0}$ such that

$$
0 \leq \nu_{0} \leq d, 1 \leq \mu_{0} \leq s\left(\nu_{0}\right)
$$

and

$$
b_{\nu_{0}, \mu_{0}} \gg d^{1 / 2} .
$$

Theorem 5 is proved by means of Klein polygons. The same result is true for real-valued (not integer) almost arithmetic progressions and in the last case $S$. Konyagin showed that the result for real-valued progressions is exact in order.
1.2. Simultaneous approximations. Let $\psi: \mathbb{R}_{+} \rightarrow \mathbb{R}_{+}$be a positive and real-valued function. For given $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right) \in \mathbb{R}^{s}$, a positive integer $p$ is said to be a $\psi$-approximation of $\alpha$, if

$$
\max _{j=1, \ldots, s}\left\|p \alpha_{j}\right\|=\max _{j=1, \ldots, s} \min _{a \in \mathbb{Z}}\left|p \alpha_{j}-a\right| \leq \psi(p)
$$

1.2.1. Dirichlet and Liouville's theorems. Dirichlet's theorem states that for any $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right) \in \mathbb{R}^{s}$, where $1, \alpha_{1}, \ldots, \alpha_{s}$ linearly independent over $\mathbb{Z}$, there are infinitely many $\psi$-approximations of $\alpha$ with $\psi(y)=y^{-1 / s}$.

On the other hand, Liouville's theorem ([2], ch.5) shows that for any $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right) \in \mathbb{R}^{s}$ such that $1, \alpha_{1}, \ldots, \alpha_{s}$ form a basis of a real algebraic field of degree $s+1$, there exists $C(\alpha)$ such that

$$
\max _{j=1, \ldots, s}\left\|p \alpha_{j}\right\| \geq C(\alpha) p^{-1 / s}, \quad \forall p \in \mathbb{N}
$$

One can see that there are only countably many algebraic $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right)$.
1.2.2. Theorem by Cassels and Davenport and the result by Jarnik. In [3, 6] the following result is obtained.

Theorem 6. There exists a constant $C_{s}$ for which there exists an uncountable set of elements $\alpha \in \mathbb{R}^{s}$ which do not have any $\psi$-approximation where $\psi(y)=C_{s} y^{-1 / s}$.
V. Jarnik [12, 13] proved another result:

Theorem 7. Let $\psi$ and $\lambda$ be positive real-valued functions such that $\psi(y) y^{1 / s}$ decreases as $y \rightarrow \infty$ and $\lambda(y) \rightarrow 0$ as $y \rightarrow \infty$. Then there exists an uncountable set of elements $\alpha \in \mathbb{R}^{s}$ for which there are infinitely many $\psi$ approximations, but only finitely many $\psi \lambda$-approximations.

A review of other results can be found in $[43,10,2]$.
1.2.3. Exact results in terms of the order of approximation. Generalizing the work [3] by means of chains of parallelepipeds [28, 50, 7, 8] we improve Jarnik's result.

Theorem 8. For $y \geq 1$, let $\psi$ and $\omega$ such that Let $\psi(y)=y^{-1 / s} \omega(y)$, where $\omega(y)$ decreases as $y \rightarrow \infty$ and

$$
\omega(1) \leq 2^{-(s+1)(s+2)}(s!)^{-1 / s}
$$

Then there exists a vector $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right)$ which has infinitely many $\psi$ approximations but not any $2^{-(s+3)} \psi$-approximation.

Theorem 9. Let $\omega$ and $\psi$ be as in Theorem 8 and suppose that

$$
\omega(1) \leq 2^{-(s+1)(s+3)}(s!)^{-1 / s} .
$$

Then there exists an uncountable set of vectors $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right)$, each of them having infinitely many $\psi$-approximations but not any $2^{-(s+3)} \psi$ approximation.

It follows that in Cassels Theorem 6 we may put

$$
C_{s}=2^{-(s+2)(s+3)}(s!)^{-1 / s}
$$

We say that $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right)$ satisfies the $\psi$-condition if $\alpha$ has infinitely many $\psi$-approximations but not any $c \psi$-approximation for some $c=c(\alpha)$

Theorem 10. Let $\psi$ be defined by $\psi(y)=y^{-1 / s} \omega(y)$ where $\omega$ is decreasing positive function. Then in any Jordan s-dimensional domain $\Omega$ with Vol $\Omega>0$, there exists an uncountable set of $\alpha \in \mathbb{R}^{s}$ satisfying the $\psi$ condition.

Theorems 8, 9, 10 are discussed in [33].
1.2.4. Successive best approximations. Let $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right) \in \mathbb{R}^{s}$. We define $a$ best simultaneous approximation (b.a) of $\alpha$ to be any integer point $\zeta=\left(p, a_{1}, \ldots, a_{s}\right) \in \mathbb{Z}^{s+1}$ such that $\forall q, \forall\left(b_{1}, \ldots, b_{s}\right) \in \mathbb{Z}^{s}, 1 \leq q \leq p$, $\left(q, b_{1}, \ldots, b_{s}\right) \neq\left(p, a_{1}, \ldots, a_{s}\right)$, we have

$$
D(\zeta)=\max _{j=1, \ldots, s}\left|p \alpha_{j}-a_{j}\right|<\max _{j=1, \ldots, s}\left|q \alpha_{j}-b_{j}\right|
$$

Let $\alpha_{j} \notin \mathbb{Q}, j=1, \ldots, s$. Then all b.a. of $\alpha$ form infinite sequences

$$
\zeta^{\nu}=\left(p^{\nu}, a_{1}^{\nu}, \ldots, a_{s}^{\nu}\right), \quad \nu=1,2, \ldots
$$

where $p^{1}<p^{2}<\ldots<p^{\nu}<p^{\nu+1}<\ldots$ and

$$
D\left(\zeta^{1}\right)>D\left(\zeta^{2}\right)>\ldots>D\left(\zeta^{\nu}\right)>D\left(\zeta^{\nu+1}\right)>\ldots
$$

Let

$$
M_{\nu}[\alpha]=\left(\begin{array}{cccc}
p^{\nu} & a_{1}^{\nu} & \ldots & a_{s}^{\nu} \\
\ldots & \ldots & \ldots & \ldots \\
p^{\nu+s} & a_{1}^{\nu+s} & \ldots & a_{s}^{\nu+s}
\end{array}\right)
$$

For $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right)$ satisfying $\alpha_{j} \notin \mathbb{Q}, j=1, \ldots, s$, we define $R(\alpha) \in$ $[2, s+1]$ to be the integer

$$
\begin{aligned}
& R(\alpha)=\min \left\{n: \text { there exist a lattice } \Lambda \subseteq \mathbb{Z}^{s+1} \text { with } \operatorname{dim} \Lambda=n\right. \\
& \text { and a natural } \left.\nu_{0} \text { such that } \zeta^{\nu} \in \Lambda, \forall \nu>\nu_{0}\right\} \text {. }
\end{aligned}
$$

Proposition 11. Let $s=1$. Then for any $\nu \geq 1$ we have $\operatorname{det} M_{\nu}[\alpha]= \pm 1$ $\left(\operatorname{rank} M_{\nu}[\alpha]=2, \forall \nu\right)$.

Proposition 12. For any $s \geq 1$ we have $R(\alpha)=\operatorname{dim}_{\mathbb{Z}}\left(\alpha_{1}, \ldots, \alpha_{s}, 1\right)$.

Proposition 13. Let $s=2$ and $\alpha_{1}, \alpha_{2}$ such that $1, \alpha_{1}, \alpha_{2}$ are linearly independent over $\mathbb{Z}$. Then for infinitely many $\nu$ we have

$$
\operatorname{rank} M_{\nu}[\alpha]=3=\operatorname{dim}_{\mathbb{Z}}\left(\alpha_{1}, \alpha_{2}, 1\right)
$$

Proposition 11 - 13 can be easily verified. The following result is proved in [36].

Theorem 14. Let $s \geq 3$. There exists an uncountable set of elements $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right) \in \mathbb{R}^{s}$ such that
(i) $1, \alpha_{1}, \ldots, \alpha_{s}$ are linearly independent over $\mathbb{Z}$,
(thus $\left.\operatorname{dim}_{\mathbb{Z}}\left(\alpha_{1}, \ldots, \alpha_{s}, 1\right)=s+1\right)$,
and
(ii) $\operatorname{rank} M_{\nu}[\alpha] \leq 3, \forall \nu \geq 1$,
(Hence for all $\nu \geq 1$ we have $\operatorname{det} M_{\nu}[\alpha]=0$ ).
Theorem 14 represents a counterexample to the conjecture of J.S. Lagarias [26]. It shows that the successive b.a. have no such an asymptotic property as a reader can see in Proposition 12. The idea of the proof was suggested to the author by N.P. Dolbilin.
1.3. Linear forms. Again, let $\alpha_{1}, \ldots, \alpha_{s}$ be real numbers such that $1, \alpha_{1}$, $\ldots, \alpha_{s}$ are linearly independent over $\mathbb{Z}$, and put $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right)$.
For $m=\left(m_{0}, m_{1}, \ldots, m_{s}\right) \in \mathbb{Z}^{s+1} \backslash\{0\}$ we define

$$
\zeta(m)=m_{0}+m_{1} \alpha_{1}+\cdots+m_{s} \alpha_{s}, \quad M=\max _{j=0,1, \ldots, s}\left|m_{j}\right|
$$

A vector $m \in \mathbb{Z}^{s+1} \backslash\{0\}$ is a best approximation of $\alpha$ in sense of linear form if

$$
\zeta(m)=\min _{\substack{n \in \mathbb{Z}^{s+1}\left\{\{0\} \\ \max _{j}\left|n_{j}\right| \leq M\right.}}|\zeta(n)|
$$

All best approximations form sequences

$$
\begin{gathered}
\zeta_{1}>\zeta_{2}>\cdots>\zeta_{\nu}>\zeta_{\nu+1}>\ldots \\
M_{1}<M_{2}<\cdots<M_{\nu}<M_{\nu+1}<\ldots
\end{gathered}
$$

where $m_{\nu}=\left(m_{0, \nu}, \ldots, m_{s, \nu}\right)$ is the vector of the $\nu$-th b.a., $\zeta_{\nu}=\zeta\left(m_{\nu}\right)$ and $M_{\nu}=\max _{j}\left|m_{j, \nu}\right|$.

By Minkowski's Theorem we have $\zeta_{\nu} M_{\nu+1}^{s} \leq 1$.
1.3.1. Singular systems. The theorem on the order of approximations from §1.1.2 does not admit multidimensional generalization in the sense of linear form.

Theorem 15 (see [29, 35]). Let $s$ be an integer $\geq 1$ and $\psi$ a function such that $\psi(y)$ decreases to zero when $y$ tends to infinity. Then there exists an uncountable set of elements $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right) \in \mathbb{R}^{s}$ such that
(i) $1, \alpha_{1}, \ldots, \alpha_{s}$ are linearly independent over $\mathbb{Z}$,
and
(ii) the sequence of the best approximations of $\alpha$ satisfies

$$
\zeta_{\nu} \leq \psi\left(M_{\nu+s-1}\right)
$$

In the case $s=1$ this theorem means that there are real numbers with any given order of the best approximations. In higher dimensions it gives something more.

Khinchin [15] defined a vector $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right) \in \mathbb{R}^{s}$ to be a $\psi$-singular system if for any $T>0$ the system

$$
\left\|m_{1} \alpha_{1}+\cdots+m_{s} \alpha_{s}\right\|<\psi(T), \quad M=\max _{1 \leq j \leq s}\left|m_{j}\right|<T
$$

has a nontrivial solution $\left(m_{1}, m_{2}, \ldots, m_{s}\right) \in \mathbb{Z}^{s}$.
Proposition 16. System is $\psi$-singular $\Longleftrightarrow \zeta_{\nu}<\psi\left(M_{\nu+1}\right), \forall \nu$.
1.3.2. Successive best approximations for linear form. Here we define $\Delta_{\nu}^{s}$ to be the determinant of the successive best approximations

$$
\Delta_{\nu}^{s}=\left|\begin{array}{cccc}
m_{0, \nu} & m_{1, \nu} & \ldots & m_{s, \nu} \\
\ldots & \ldots & \ldots & \ldots \\
m_{0, \nu+s} & m_{1, \nu+s} & \ldots & m_{s, \nu+s}
\end{array}\right|
$$

The proposition below follows from Minkowski theorem on convex body. It seems to me that it is a well-known fact, but I could not find the corresponding reference.

Proposition 17. Let $s=2$. Then for infinitely many $\nu$ we have $\Delta_{\nu}^{2} \neq 0$.
The theorem below was proved by the author in [35] by means of singular systems.

Theorem 18. Lets $\geq 3$. Then there exists a uncountable set of vectors $\alpha=\left(\alpha_{1}, \ldots, \alpha_{s}\right) \in \mathbb{R}^{s}$ such that
(i) $1, \alpha_{1}, \ldots, \alpha_{s}$ are linearly independent over $\mathbb{Z}$,
and
(ii) there exists a linear subspace $\mathcal{L}_{\alpha} \subset \mathbb{R}^{s+1}, \operatorname{dim} \mathcal{L}_{\alpha}=3$ satisfying the condition

$$
m_{\nu} \in \mathcal{L}_{\alpha}, \quad \forall \nu>\nu_{0}
$$

We see that for $s \geq 3$ almost all best approximations may asymptotically lie in a three-dimensional plane but they cannot lie in two-dimensional plane. Of course these examples are degenerated in sense of measure. For almost all vectors $\alpha \in \mathbb{R}^{s}$ (in the sense of Lebesgue) best approximations are asymptotically $(s+1)$-dimensional.

## 2. Integrals from quasiperiodic functions

In the text below we discuss applications of diophantine results to certain problems of uniform distribution of irrational rotations on torus. A full review of the methods and results of the theory of uniform distribution is given in [25].
2.1. Uniform distribution. Let $\mathbf{T}$ be the one-dimensional torus and $f$ : $\mathbf{T}^{s} \rightarrow \mathbb{R}$ defined by the series

$$
f\left(x_{1}, \ldots, x_{s}\right)=\sum_{\substack{m \in \mathbb{Z}^{s} \\ m \neq 0}} f_{m} \exp \left(2 \pi i\left(m_{1} x_{1}+\cdots+m_{s} x_{s}\right)\right)
$$

We also define the integral

$$
I(T, \varphi)=I_{f, \omega}(T, \varphi)=\int_{0}^{T} f\left(\omega_{1} t+\varphi_{1}, \ldots, \omega_{s} t+\varphi_{s}\right) d t
$$

where $\omega_{1}, \ldots, \omega_{s} \in \mathbb{R}$ are linearly independent over $\mathbb{Z}$, and $\varphi=\left(\varphi_{1}, \ldots, \varphi_{s}\right)$ $\in \mathbb{R}^{s}$.
H. Weyl [51] proved that if $f$ is a continuous function, then for any $\varphi$ we have $I(T, \varphi)=o(T), \quad T \rightarrow \infty$. This equality holds uniformly in $\varphi$ if we suppose moreover that $f$ is smooth.
V.V. Kozlov conjectured that the integral $I(T, \varphi)$ is recurrent that is the following condition holds:

$$
\begin{equation*}
\forall \varepsilon>0, \quad \forall T, \quad \exists T^{*}>T:\left|I\left(T^{*}, \varphi\right)\right|<\varepsilon \tag{*}
\end{equation*}
$$

This conjecture is true when $f$ is any trigonometric polynomial, and in this case ( $*$ ) holds uniformly in $\varphi$. This implies that for any trigonometric polynomial $f$ of finite degree, $J^{\infty}$ defined by

$$
J^{\infty}(T)=J_{f, \omega}^{\infty}(T)=\sup _{\varphi \in \mathbb{R}^{s}}|I(T, \varphi)|
$$

is itself recurrent, that is

$$
\forall \varepsilon>0, \quad \forall T, \quad \exists T^{*}>T:\left|J^{\infty}\left(T^{*}\right)\right|<\varepsilon
$$

2.2. Case $s=2$. In the two-dimensional case, the conjecture above was proved by V.V. Kozlov himself for functions $f \in C^{2}\left(\mathbf{T}^{2}\right)$ in [18] (see also [19]). It is also easy to see that when $f$ is a smooth function, then (*) holds uniformly in $\varphi$, that is (\$) is true. E.A. Sidorov [44] obtained a similar result for "absolutely" continuous $f$.
2.3. The general result. The author [34] proved the conjecture in the general case:

Theorem 19. Suppose that

$$
f\left(x_{1}, \ldots, x_{s}\right)=\sum_{\substack{m \in \mathbb{Z}^{s} \\ m \neq 0}} f_{m} \exp \left(2 \pi i\left(m_{1} x_{1}+\ldots+m_{s} x_{s}\right)\right)
$$

belongs to the class $C^{d}\left(\mathbf{T}^{s}\right)$, where $d>C s^{s^{3}}$ and $\omega_{1}, \ldots, \omega_{s}$ are linearly independent over $\mathbb{Z}$. Then for any $\varphi$, the integral $I(T, \varphi)$ satisfies (*).

The proof is based on consideration of best approximations in the sense of linear form (see §1.3.2.).
2.4. Metric results. It is known [49, 48] that for almost all (in the sense of Lebesgue) vectors $\omega=\left(\omega_{1}, \ldots, \omega_{s}\right) \in \mathbb{R}^{s}$, if $f$ is smooth enough, then the integral $I(T, \varphi)$ is bounded when $T \rightarrow \infty$ uniformly in $\varphi$. Hence the integral $I(T, \varphi)$ satisfies (*), uniformly in $\varphi$. But even in the case $s \geq 3$, this result is not universal.

Let $\Phi$ be a decreasing function and assume that the series $\sum_{m \in \mathbb{Z}} \Phi(m)$ converges. We define a periodic function $\Theta: \mathrm{T}^{s} \rightarrow \mathbb{R}$ to be of the type $\Phi$ if, the coefficients $\Theta_{m_{1}, \ldots, m_{s}}$ in the expansion

$$
\Theta\left(x_{1}, \ldots, x_{s}\right)=\sum \Theta_{m_{1}, \ldots, m_{s}} e^{2 \pi i m_{1} x_{1}+\cdots+m_{s} x_{s}},
$$

satisfy

$$
\left|\Theta_{m_{1}, \ldots, m_{s}}\right| \leq \Phi(M), \quad \text { where } M=\max _{j}\left|m_{j}\right|
$$

We consider

$$
\begin{gathered}
J^{\infty}(T)=J_{f, \omega}^{\infty}(T)=\max _{\varphi \in \mathbf{T}^{s}}\left|I_{f, \omega}(T, \varphi)\right| ; \\
J^{2}(T)=J_{f, \omega}^{2}(T)=\left(\int_{T^{s}}\left|I_{f, \omega}(T, \varphi)\right|^{2} d \varphi\right)^{1 / 2}
\end{gathered}
$$

The result below is proved in [29].
Theorem 20. Let $s \geq 3$. Then for any function $\Phi$ which decreases to zero as $y \rightarrow \infty$ and for any function $\psi$ with $\psi(y)=o(1)$ as $y \rightarrow \infty$, there exist $\omega_{1}, \omega_{2}, \ldots, \omega_{s}$ which are linearly independent over $\mathbb{Z}$, and a function $f$ of type $\Phi$ such that $\int_{\mathbf{T}^{s}} f(x) d x=0$ and

$$
J^{l}(T) \gg T \psi(T) \quad \forall T, \quad l=2, \infty
$$

We will reformulate Theorem 20 in the following way.

Theorem 21. Let $s \geq 3$, and $f: \mathbf{T}^{s} \rightarrow \mathbb{R}$ be smooth with zero mean value. Assume that in the expansion

$$
f\left(x_{1}, \ldots, x_{s}\right)=\sum_{\left(m_{1}, \ldots, m_{s}\right) \neq 0} f_{m_{1}, \ldots, m_{s}} e^{2 \pi i\left(m_{1} x_{1}+\cdots+m_{s} x_{s}\right)}
$$

the coefficients $f_{m_{1}, \ldots, m_{s}}$, where $\left(m_{1}, \ldots, m_{s}\right) \neq 0$, are all different from zero.
Then there exist $\omega_{1}, \omega_{2}, \ldots, \omega_{s}$ which are linearly independent over $\mathbb{Z}$ such that

$$
J^{l}(t) \gg t \psi(t) \quad \forall t ; \quad l=2, \infty
$$

An improvement of the latter result was obtained recently by E.V. Kolomeikina [20].

One can see that the behaviour of integrals $J_{l}$ in two-dimensional case radically differs from the case $s \geq 3$.
2.5. Odd functions. Sergei Konyagin's result. Recently, S. Konyagin [16] obtained the following result.
Theorem 22. The Kozlov's conjecture is true (that is (*) holds) for arbitrary $s \geq 1$ and any function $f$ satisfying the condition

$$
f\left(-x_{1}, \ldots,-x_{s}\right)=f\left(x_{1}, \ldots, x_{s}\right), \quad f \in C^{\tau}\left(\mathbf{T}^{s}\right), \tau \asymp s 2^{s}
$$

2.6. The smoothness. In [42],[41] it is shown that we need some kind of smoothness conditions on $f$ to insure that (*) is true : indeed in the twodimensional case $(s=2)$, there exists a function $f: \mathbf{T}^{2} \rightarrow \mathbb{R}$ (with zero mean value) of the class $C \backslash C^{1}\left(\mathbf{T}^{2}\right)$ such that $I(T, 0)$ tends to infinity when $T \rightarrow \infty$ (with the choice $\omega_{1}=1$ and $\omega_{2}=\sqrt{2}$ ). On the other hand, in [44] it is shown that when $s=2$, a sufficient condition on $f$ for having (*), is $f$ to be absolutely continuous.

Developping an idea of D.V. Treshchev, the author, in [31], generalized Poincaré's example. He proved that for any real $\omega_{1}, \ldots, \omega_{s}$ which form a basis of a real algebraic field, there exists a function $f \in C^{s-2}\left(T^{s}\right) \backslash C^{s-1}\left(T^{s}\right)$ such that $I(., 0)$ does not satisfy the property $(*)$ with $\varphi=0$.

One may find some results on algebraic numbers in [40] and [38]. Recently, S.V. Konyagin [16] proved that for some Liouville transcendental numbers, there exists $f \in C^{d}\left(T^{s}\right)$ with $d \asymp 2^{s} / s$ such that (*) is not satisfied.

Some early results are reviewed in [37].
2.7. Vector-functions: counterexample in dimension $s=3$. Let $f^{j}$ : $\mathrm{T}^{s} \rightarrow \mathbb{R}, j=1,2$ be defined by

$$
f^{j}\left(x_{1}, \ldots, x_{s}\right)=\sum_{\substack{k \in \mathcal{Z}^{s} \\ k \neq 0}} f_{k}^{j} \exp \left(2 \pi i\left(k_{1} x_{1}+\cdots+k_{s} x_{s}\right)\right)
$$

For $\omega_{1}, \ldots, \omega_{s} \in \mathbb{R}$ be linearly independent over $\mathbb{Z}$, we put

$$
I^{j}(T)=\int_{0}^{T} f^{j}\left(\omega_{1} t, \ldots, \omega_{s} t\right) d t, \quad j=1,2
$$

The analogue of property (*) for the vector-integral $I=\left(I^{1}, I^{2}\right): \mathbb{R} \rightarrow \mathbb{R}^{2}$ becomes

$$
\forall \varepsilon>0 \forall T \exists T^{*}>T:\left|I^{1}\left(T^{*}\right)\right|+\left|I^{2}\left(T^{*}\right)\right|<\varepsilon
$$

Proposition 23. In the case when $s=2$ and $f$ is a smooth vector-functions, then (\%) holds.

Proposition 24. The analogue of Theorem 22 holds for vector-function, that is (\%) is satisfied for any odd smooth vector-function $f$.

Let $\Phi: \mathbb{R}_{+} \rightarrow \mathbb{R}_{+}$be a positive function such that $\sum_{k \in \mathbb{Z}^{s}} \Phi\left(\max _{1 \leq j \leq s}\left|k_{j}\right|\right)$ converges. A vector-function $f=\left(f^{1}, f^{2}\right): \mathbf{T}^{s} \rightarrow \mathbb{R}^{2}$ is defined to be a function of type $\Phi$ if we have

$$
\left|f_{k}^{j}\right| \leq \Phi\left(\max _{1 \leq j \leq s}\left|k_{j}\right|\right) \quad \forall k, \quad j=1,2
$$

Recently, the author [34] constructed the following example.
Theorem 25. For any given positive function $\Phi$, there exist a vector-function $f=\left(f^{1}, f^{2}\right): \mathbf{T}^{3} \rightarrow \mathbb{R}^{2}$ of the type $\Phi$ with zero mean value $\left(\int_{\mathbf{T}^{3}} f^{j}(x) d x\right.$ $=0, j=1,2)$ and numbers $\omega_{1}, \omega_{2}, \omega_{3}$, which are linearly independent over $\mathbb{Z}$ such that

$$
\left|I^{1}(T)\right|+\left|I^{2}(T)\right| \rightarrow \infty, \text { as } T \rightarrow+\infty
$$

Acknowledgment. The author thanks prof. M. Waldschmidt and prof. P. Voutier for their help in checking the language of the paper.
